The ninth twenty-four hours, temperature 90 to 102, pulse 108 to 120 and bounding. Respiration 24. Total urine 45 ounces. Quality of urine same, except that it is now perfectly clear. No explanation could be found for the rise in temperature and pulse rate. One physician who saw the patient at this time stated that the pulse was that of a patient just previous to puerperal eclampsia and advised the use of a veratrum viride. This was not given, however.

The tenth day, temperature 99 to 101, pulse 80 to 100, respiration 24. Total amount of urine 44 ounces. General strength improved, patient feels better and asked to get up. Quality of urine the same as on sixth day.

During the eleventh day the total amount of urine was 47 ounces; during the twelfth day 52 ounces; during the thirteenth day 48 ounces; during the fourteenth day 78 ounces; during the fifteenth day 62 ounces; during the sixteenth day 65 ounces; during the seventeenth day 47 ounces; during the eighteenth day 64 ounces; during the nineteenth day 80 ounces. On this date the patient returned to her home, and the husband has reported that the total amount of urine has averaged from four to four and one-half pints per day for every day since March 25.

The temperature returned to normal after the tenth day and remained so. The strength of the patient improved steadily, and she sat up on the sixteenth day after operation. The appetite improved rapidly until it became normal. The urine became normal on the seventeenth day.

It is believed that this patient suffered from a vasomotor suppression of urine. There are two factors which may have acted in a causative relationship to the condition. Either the ergot which was contained in the emmenagogue caused a strong and persistent vaso-constriction, or a strong reflex was communicated to the kidney at the time of the destruction of the ovum or by the uterine irrigation. Neither of these could be called an overpowering reflex, and it is certainly true that such a result would be most unusual, yet at the same time we must take into consideration the fact that the susceptibility of the nervous system to irritation and to reflex, particularly in women, is a most variable quantity. The patient was not exposed to conditions which would cause an acute nephritis, nor did she present the slightest symptom of this disease at any time. She was perfectly well up to the time of the destruction of the ovum. The temperature which she presented at the time of Dr. Perry's first visit is not believed to have been the result of septic infection, since it disappeared after one flushing of the uterus, and the material found in the uterus at the time of curettage did not seem to be infected. It is, of course, possible that there was some absorption of decomposition products into the general circulation, yet in the absence of any disturbance of the temperature and pulse rate it is difficult to believe that these products were very poisonous.

GENERAL CONSIDERATIONS.

The writer has been impressed on more than one occasion by the fact that our ready reference text-books of surgery contain little or no mention of the subject of suppression of urine. The condition is given a brief mention as a symptom, in connection with certain surgical diseases of the kidney and ureter, but is nowhere discussed in full, in so far as he knows, as a definite condition entitled to elaboration from the viewpoints of etiology, diagnosis and treatment. The literature on this subject, even though meager, is valuable and should be collected into such available form as will give a definite classification and a clear exposition of the subject. It has been the unfortunate experience of the writer to encounter this condition in a variety of forms; indeed, every surgeon has his quota of deaths after operation from suppression of urine and every surgeon knows the anxiety that is felt during the hours of its possibility and of its endurance.

It has been stated that suppression of urine is merely a symptom and not a disease. It is certainly true that suppression of urine may be but a single symptom in the picture of a given disease, e. g., cancer of the uterus with involvement of the ureters, but it is likewise true that in the majority of cases which are presented to the surgeon the suppression of urine is the one condition which imperatively demands treatment, and the one condition which is going to kill the patient unless relieved. Furthermore, each case of suppression of urine must be accurately and painstakingly studied from the viewpoints of etiology, pathology, symptoms, diagnosis and treatment, and it requires but slight reflection to see that the investigation and the management of these cases present unusual difficulties.

Such, it seems to the author, are the claims of this subject to a place among surgical conditions.

The present paper does not present for your consideration a solution to the problems of suspended kidney function, nor does it furnish a full presentation of the subject. The case, which is recorded above, is offered as a contribution to the meager literature on this subject, while the appended general discussion is presented in the purely suggestive light of personal impression gained from clinical experience and from some reading.

DEFINITION.

Suppression of urine is commonly defined as a condition in which the excretion of urine from the tubules of the kidney is entirely suspended or in which no urine is transmitted to the bladder. This definition is made to cover two distinct conditions and is believed by the author to be open to criticism. It would seem more accurate to omit the latter clause and say that suppression of urine is a condition in which the excretion of urine from the parenchyma of the kidney is suspended. When one or both ureters are mechanically obstructed the parenchyma of the kidney continues to perform its functions until a quantity of urine varying from a few ounces to one gallon has been secreted and until the pressure has become sufficiently great to arrest secretory pressure. When the urethra is mechanically obstructed the same accumulation of urine occurs behind the obstruction and the same result may follow in the kidney. Yet an accumulation of urine behind an urethral obstruction is called retention of urine, that behind an ureteral obstruction a suppression of urine, and the two are carefully differentiated. To my mind they are in reality one and the same lesion, except for the location in the tract of the obstruction, in the seriousness of the condition and in the accessibility of the lesion. The one may be diagnosticated and relieved by urethral, the other by ureteral examination and catheterization. Furthermore, the correct surgical treatment in each case is directed to the seat of mechanical obstruction with the one purpose of liberating the pent-up kidney secretions and of preventing or relieving serious secondary lesions in the kidneys.

In suppression of urine, as defined, the secreting mechanism itself is at fault; the lesion is primary in the kidney, and no urine is separated from the blood. The treatment of the condition must be based on entirely different grounds, and the lesion must be studied from the physiologic side.

We have, then, two distinct conditions, the one mechanical and always surgical, the other physiologic and sometimes surgical, and each worthy of careful study from the viewpoint of etiology and pathology. An appropriate division of that condition in which no urine is discharged from the body would seem to be: 1. Vesical and urethral retention or obstruction of urine. 2. Ureteral retention or obstruction of urine. 3. Suppression of urine.

It is believed by the writer that the above modifications in the definition of suppression of urine or anuria should be made. Yet the present discussion of the condition will be pursued according to the usual definition and a division of the subject will be made into an obstructive and non-obstructive form, each of which ma be elaborated under the heading of etiology.

ETIOLOGY.

The condition presented to the physician is one o "no urine," and it becomes necessary for him to seek th cause of this condition. The following table is offere as a concise statement of the causes of suppression o urine.

I. Obstructive suppression of urine may result from:

- *A.* A calculus, a blood clot or a plug of pus in the ureter. This may cause complete obstruction.
  - (*a*) In the ureter of the only existing kidney.
  - (*b*) In a single fused ureter from the two kidneys or from a horseshoe kidney.
  - (*c*) In the ureter of the only functionating kidney, the other kidney having been previously destroyed by calculous obstruction, tuberculosis, nephrolithiasis, suppuration, tumor, cyst, etc., etc. This is by far the most common form.
  - (*d*) From the simultaneous obstruction of both ureters (rare).
- *B.* Stricture of the ureter under the four above-named conditions.
- *C.* Kink in the ureter of a floating kidney or angular attachment of the ureter to the pelvis under similar conditions.
- *D.* Tumor of the kidney.
- *E.* Tumor of the base of the bladder or of other organ involving both ureters.
- *F.* External pressure.
  - (*a*) Myomata of the uterus.
  - (*b*) Cancer of the uterus or rectum.
  - (*c*) Abdominal tumors.
  - (*d*) Laceration of the cervix with subsequent involvement of the ureter in the cicatrix.
- *G.* Venous congestion. An excessive degree of exudate when associated with congestion of the intertubular veins may cause a degree of lateral pressure which may result in suppression. The suppression of urine in the author's case may be explained in this way.

II. Non-obstructive suppression of urine may occur as a result of:

- *A. Reflex circulatory* or *vasomotor disturbance* in the kidney. This may occur—
  - (*a*) *After operations* which concern in any way the complex sympathetic nervous mechanism of the abdominal cavity, *e. g.*, nephrectomy, nephrotomy, operations on the bladder, operations on the male or female genital tract.
  - (*b*) After the *passage of a catheter* or a sound into the bladder. This agent may act either as a reflex or as a septic infection.
  - (*c*) As a result of the *lodgment of a calculus* in one ureter, the other remaining free. The reflex in this case may result either from the nerve irritation at the site of lodgment of the calculus or from the acute tension which occurs within the pelvis of the obstructed kidney.
  - (*d*) *Trauma*, subcutaneous or direct. In a case related by Dr. Oliver, a bullet merely cut a groove in the convexity of one kidney yet the patient died from suppression of urine.
  - (*e*) *Hysteria.*
  - (*f*) *Drug vaso-constriction, e. g., ergot,* auto-nephrotoxins.
  - (*g*) *Extensive burns,* may act either by a reflex or by sepsis.
  - (*h*) *Meningitis.* (A case reported by Fussell, in *Pediatrics*, August, 1901.)
- *B. Degenerative changes in the kidney.* These may result from:
  - (*a*) Poisoning by drugs such as phosphorus, carbolic acid, cantharides, turpentine, etc., possibly by ether and chloroform when used for surgical anesthesia.

- (b) Acute infectious diseases such as septicemia, cholera, scarlet fever, dysentery, etc.
- (c) Acute nephritis.
- (d) Auto-nephrotoxins. This is a toxic product, a *cytotoxin*, which is formed as a result of active disintegration in one kidney and which acts to produce marked degenerative changes in the opposite sound kidney. Castaigne and Rathery suggest that perchance certain renal disturbances now described as the result of reno-renal reflex nervous influences or as sympathetic nephritis are the outcome rather of *auto-nephrotoxins.*
- (e) Tubercular or cystic disease of both kidneys may progress *to the total destruction* of all secreting tissue.

C. *The direct effect of lessened heart force.* When the aortic pressure sinks below 40 mm. Hg. *the urinary secretion stops absolutely.* So long as the blood pressure is above this height the secretion is more or less proportional to the pressure, and changes with the changes in this pressure.

D. *Trauma.*
- (a) Direct paralyzing injury to both kidneys or to one kidney when the other is non-functionating.
- (b) Rupture of the *kidney,* the *ureters,* or the *bladder* with extravasation into the tissues of all urine secreted. This must be included under the old definition of suppression of urine, but is not believed to belong to the subject at all.

E. *Anesthesia.* It would be very difficult to classify this etiologic factor more accurately, for the reason that we do not certainly know the exact manner in which these drugs act on the kidney. Kemp concludes that ether, while producing a rise in *general arterial pressure, manifests a deleterious and* specific influence in a lowered renal pressure and almost immediate diminished secretion, whereas chloroform, when producing a decrease in carotid pressure, exerts but an insignificant effect if any on the renal pressure or excretion. On the other hand, Galleazi and Grillo maintain that the diminution of renal permeability is more marked when chloroform is used than when ether is administered, and they claim that this result renders any infectious disease with which the patient so anesthetized may be affected more severe.

PATHOLOGY.

A complete study of the pathologic lesions mentioned above as etiologic factors would be both impracticable and undesirable in the present paper. The pathology of those conditions enumerated under the heading of obstructive suppression is so well understood and so well described in all text-books of pathology that its recapitulation is considered unnecessary. The same may be said of some of the conditions included under the heading of non-obstructive suppression, yet it is this particular section of the subject which presents the perplexing questions, and hence it is this section which should receive most attention.

In view of the fact that we are dealing with alterations in the functional value of the specific parenchyma of the kidney, it is certainly true that we will find a physiologic basis to be the correct one on which to construct our pathologic and therapeutic superstructure.

PHYSIOLOGIC CONSIDERATIONS.

The kidney is a compound tubular gland in which the vascular apparatus is so arranged as to afford (a) the most favorable conditions for filtration of the liquid parts of the blood, and (b) the most favorable conditions for the elimination of the waste products of body metabolism by its specific excretory cells. The secretion of this gland is complex in its composition, contains most of the end products of the varied metabolism of the tissues and represents the most vital excretory product of the body. This secretion may be looked on as a solution of a great number of organic and inorganic substances in water.

The nerve supply of the kidney is vasomotor (vaso-constrictor and vaso-dilator) and secretory. The vessels of the kidney, like those of all parts of the body, are under the direct control of the central nervous system. The secretory nerves are not fully understood. The nerves are definite off-shoots from and an integral part of the vast abdominal sympathetic system, and are connected with the spinal cord through the anterior roots of the eleventh, twelfth and thirteenth dorsal nerves. These nerves enter the hilum of the kidney both as a plexus closely investing the renal artery and as fibers which run parallel to the vessels and can be traced as far as the cortex.

The secretion of urine consists of two distinct processes: (1) The secretion of water and salts, and (2) the elimination of urea and related bodies. The secretion of the waters and the inorganic salts undoubtedly takes place through the glomerulus. The excretion of urea and related bodies is believed to take place through the agency of the epithelial cells lining the convoluted tubules. These cells perform the function of secreting the specific nitrogenous elements of the urine, which are taken up into solution by the water which flows downward from the glomerulus and a completed urine is formed.

The secretion of water and inorganic salts seems to be largely, yet not entirely, a question of mechanical filtration or separation and to depend mainly on two factors.

(1) The difference of pressure between the blood in the glomerular capillaries and the urine in Bowman's capsule. The pressure in the tubule is practically *nil* under normal circumstances, so that the only changeable factor will be the blood pressure in the capillaries.

(2) The rapidity of the blood flow through the glomeruli. The more frequently the fluid is presented to the filter the more rapidly will the process go on.

The glomerular circulation may be affected in several ways. The pressure in the glomerular capillaries will be raised and the velocity of the blood increased:

(1) By a rise in the general blood pressure. This may be due to (a) increased force and frequency of the heart, (b) constriction of vascular areas in other parts of the body.

(2) By dilatation of the renal arterioles, the general blood pressure remaining constant.

(3) By obstructing the renal vein. In this case the velocity will be diminished.

The pressure and velocity in the glomerular capillaries will be diminished:

(1) By diminished general blood pressure, which may arise from a weakening or slowing of the heart beat, or from dilatation of vascular areas in other parts of the body.

(2) By constriction of the vessels in the kidney itself.

As has been stated above, a diminution of aortic pressure below 40 mm. Hg. results in an absolute cessation of secretion and variations in pressure above this point will be followed by corresponding variations in the amount of urine secreted.

It is to this vasomotor mechanism of the kidney that we must look for the regulation of the flow of blood through the kidney, hence for a rational explanation of variations in the secretion of urine.

Stimulation of the vaso-constrictor fibers causes contraction of the arteries of the kidney, a diminution in the size of the organ and a diminished secretion of urine. Stimulation of the vaso-dilators will have precisely the opposite effect. Both of these sets of fibers are probably brought into play under normal conditions by reflex stimulation, and thus serve to regulate the flow of blood through the kidney and thereby influence its functional activity.

It has been estimated that, in strong diuresis, 5.6 per cent. of the total quantity of blood sent out of the left heart in a minute may pass through the kidneys, although the combined weight of these organs makes only 0.56 per cent. of that of the body.

That the formation of the water of the urine is not entirely a question of filtration, however, would seem to be demonstrated by two experimental facts:

(1) Ligation of the renal vein raises the blood pressure in the glomerular capillaries almost to that of the

PATHOLOGIC CONSIDERATIONS.

lex Vasomotor Suppression of Urine.—The kidney enchyma, it will be remembered, is enclosed within firm unyielding capsule, analogous in every way to the apsule (sclera) of the eye and the bony casement of the rain. Under normal conditions a vaso-constriction diminishes the amount of blood entering this capsule, the idney capillaries become anemic, and an amount of lood escapes through the veins exactly equal to that which enters. Under normal vaso-dilator action the mount of blood entering the closed sac is exceedingly ncreased, the entire organ increases in size, the capsule ecomes tense, yet again the venous return is entirely fficient and carrys off an amount of blood exactly equal o that which enters. The blood circulation through the idney is perfect in each instance, but the amount of lood flowing through the organ is widely different. The regulation of the exact amount of blood that shall

hrough the kidney, it will be remembered, is the

n of urine will immediately stop. The kid-
ecome anemic and the blood contained in the
ll flow off through the veins. Now, it has been
strated anatomically that the kidney receives a
c anastomotic circulation through its capsule. Fur-
ermore, it has been demonstrated that simple ligature of the renal artery will cause a condition of red infarct in the kidney, while the ligature of this artery, after the complete removal of the capsule, will result in a condition of white infarct. This means that after ligature of the renal artery blood flows through this anastomotic circulation into the kidney in sufficient quantity to engorge the vessels, yet under insufficient pressure to reestablish the circulation of the blood through the organ. A condition of red infarct results. When the capsule is removed, however, this anastomotic circulation is cut off and all blood left in the kidney drains off, leaving the capillaries empty and the tissues white.

Precisely the same conditions are presented when a sudden vaso-constriction closes the vessels of the kidney. The blood flow is arrested and this same anastomotic circulation engorges the capillaries and veins of the cortex. The endothelial cells in the walls of the capillaries and the small veins have suffered a degenerative change, however, because of the arrest of blood, and they permit the serum to leak out between the tubules. Now, since it is improbable that a complete obliteration of the arterioles by vaso-constriction could endure for a very extended period of time, let us see what would happen when these arterioles begin to open again. Blood is once more pumped into the kidney, but the venous return is seriously impeded by the lateral pressure of the exudate which has formed around and between the paralyzed veins and the tubules. The congestion of the vessels of the kidney becomes more intense with each heart beat, and a condition analogous to experimental ligature of the renal vein ultimately results. The blood flow through the kidney is stagnant, no urine is secreted, the capsule becomes over-distended and tense, the blood becomes highly venous and the kidney parenchyma suffers serious degeneration from insufficient oxygen and food supply. This is precisely the lesion found at the time of operation in the kidneys of the patient whose case has been reported in this paper.

Should the overpowering stimulation of the nervous mechanism of the kidney result in either a paralysis of the vaso-constrictors or a stimulation of the vaso-dilators, the effect on the circulation would be the same and the reasoning as to the ultimate effect on the kidney of both tion revealed the presence of adhesions in 96, or 42.5 per cent.

In 123 cases of ulcer with adhesions, collected by the same authority, the pancreas was involved in 49, the liver in 23, the liver and pancreas in 10, the colon in 7, the liver and colon in 4, the spleen in 2, the mesentery in 3, and three or more organs, including, in addition to the above, the omentum, diaphragm, abdominal wall and kidney, in 15. I shall not attempt to discuss the cases where perforation has occurred with a resulting localized abscess, as the symptoms of this condition are usually acute, the septic predominating over those of disturbed function.

It is thus readily seen that the formation of adhesions between the stomach and the other abdominal organs is of such frequent occurrence in cases of chronic ulcer as to vest the subject with considerable importance.

The distribution of these adhesions is readily understood from the fact that about 80 per cent. of all gastric ulcers are situated on the posterior surface of the stomach or at the pylorus.

This, of course, brings the larger number more or less intimately in contact with the liver and pancreas and it is to one or more of these organs that we find the adhesion has most frequently occurred. As would be expected, the next most common point for their formation is the transverse colon. Adhesions to the abdominal wall, mesentery, spleen and kidney are relatively uncommon.

The area of the stomach wall involved in the inflammatory process and the density of the resulting adhesion or adhesions are subject to wide variation. We may find a small surface only which has become so fixed, with a resulting conical prolongation of the stomach in that direction or the amount adherent may be as large as the hand. Indeed, in those rare cases of plastic perigastritis the entire surface of the organ may be involved in the inflammatory process and by general widespread adhesions which so compress its walls and diminish its size as to practically put it out of commission. The adhesions may be, and usually are, very dense or, in a few instances, easily separable. In cases where they have been present for a long time and the area of the serosa involved is small, they may have lengthened out into long peritoneal bands, much resembling those found after ventro-suspension of the uterus. In such cases the normal mobility of the stomach may have been restored and the annoying symptoms spontaneously disappear.

SYMPTOMS.

The symptoms due to perigastric adhesions are often very distressing and too frequently misinterpreted. In the milder cases, where the area of the stomach wall involved is small and the adhesions are not put much on the stretch, there may be present, but vague and indefinite, digestive symptoms marked by eructations of gas and even fluid, possibly pain, and a general feeling of gastric unrest.

The symptoms, however, vary in importance and intensity with the portion of the stomach wall involved in the adhesions. If they are at or near the pylorus and seriously interfere with stomach drainage, very extreme disturbances may result. These patients will present symptoms analogous to those accompanying pyloric stenosis, i. e., dilatation of the stomach, eructation of gas and fluid and vomiting, which, in milder cases, may occur irreguarly, but in the more severe class soon follows the ingestion of food and may be so frequent and excessive as to seriously endanger life through malnutrition.

Pain is usually present in these cases and in those subject to frequent vomiting is often most intense and distressing. These patients present signs of digestive disturbances that are more or less constant and can not be relieved by ordinary methods of treatment, diet, regulation of mode of living, etc., and in those in whom the functional activity of the stomach is seriously impaired by the adhesions we find a progressive loss of weight, even extreme emaciation, and gradually increasing weakness, terminating in death from starvation and exhaustion.

DIAGNOSIS.

The diagnosis of perigastric adhesions, while presenting many difficulties, should be more frequently made, and in some cases is comparatively easy. Probably those cases will be more easily recognized where the adhesion has formed with the anterior abdominal wall. If the portion of the stomach wall involved is at a point remote from the pylorus the functional disturbance will be slight and marked chiefly by pain while the stomach digestion is at its height. Pressure over this region will elicit tenderness more or less sharply localized, which subsequent examinations will show to be constant at this point. In some patients with thin abdominal walls an area of thickening or induration may be made out.

When the pyloric end of the stomach participates in the adhesion the symptoms are usually very pronounced and may closely resemble those of pyloric stenosis. In other words, they are those resulting from dilatation of the stomach. In these patients the distress is most marked at a time corresponding to the last stage of gastric digestion. Pain appears at this time, which may soon disappear or may last for hours, and is found to exist in the right hypochondriac region. During the paroxysm the patient can bear no pressure at this point, and I have known instances where the clothing about the upper abdomen, corset, waist bands, etc., was habitually removed or loosened soon after eating to secure relief from pressure. Vomiting in these cases is an almost constant symptom and may become so constant as to actually threaten the sufferer's life, as is illustrated in Case 1. As time elapses and the dilatation of the stomach increases, owing to impaired drainage, the classical symptoms of that condition, which need not be described to you, become more and more pronounced until the condition of the sufferer is really pitiable. Palpation may in these also reveal, at the point of greatest tenderness, an area of induration. This induration may be marked and easily felt, as in Case 1, or it may be very indistinct or not demonstrable at all.

In those cases where the adhesion exists between the lesser curvature and the under surface of the left lobe of the liver the symptoms are described by Fenwick as follows:

> The chief result of the adhesion is to prevent the downward displacement and forward rotation of the stomach which normally follow the ingestion of food and to impede the contractions of its longitudinal and circular muscular fibers. This interference with the motorial functions of the organ is probably responsible for the sense of fulness and discomfort after meals, of which complaint is so often made, and for the flatulence and acidity which ensue from the use of those articles of diet that are difficult of solution or are prone to undergo fermentation.
>
> It is also to be observed that in many cases of this description the patient experiences a constant dragging pain in the epigastrium or right side of the chest, whenever he indulges in physical exertion after meals or suffers from anxiety or excite-

ment. The fact that rest in the recumbent posture or the application of an elastic belt to support the stomach affords relief appears to indicate that the pain is due to a mechanical strain on the adhesions caused by the weight of the organ or by violent contractions of its walls.

In Case 3 of the series here reported the patient, who was a carpet layer, noticed that the pain and discomfort was much augmented whenever he got down on his hands and knees to drive tacks in a carpet, and he had to give up this kind of work. The operation revealed the lesser curvature of the stomach adherent to the under surface of the left lobe of the liver, and it may readily be seen that the position above described would increase the dragging on the fixed point. I have since employed this posture as a routine measure in the examination of patients suspected of having perigastric adhesions and it has proven of considerable value as a diagnostic aid. If the adhesion is to the anterior abdominal wall, on the patient's assuming the hands and knees position the pain and sense of dragging will be relieved. If the adhesion exists between the stomach and the liver or pancreas these symptoms are much augmented.

An adhesion existing between the pylorus and the liver presents symptoms closely resembling those described when discussing the adhesion of the pyloric end of the stomach to the abdominal wall. Dilatation, with its distressing symptom complex, appears early and the functional disturbance steadily increases. In these cases the pain is a most variable symptom as to location. In Case 2 the patient complained of almost constant pain immediately under the right nipple. The pain may be most prominent immediately under the ribs on the right side of the chest, radiating from this locality to the right infrascapular region. Deep pressure over the right hypochondrium will usually reveal an area of much tenderness.

If, as frequently occurs, the pyloric end of the stomach is adherent to the gall bladder, interfering by traction on that viscus or its ducts with drainage, we may have added to the symptoms above mentioned those common to disturbance of gall-bladder function. Indeed, the signs may point more emphatically towards gall-bladder disease than to gastric disturbance, as in Case 4, when a diagnosis of cholecystitis having been made, the operation revealed an adhesion between the pylorus and the gall bladder due to a chronic gastric ulcer, the separation of which without opening the gall bladder was followed by complete subsidence of the troublesome symptoms.

In very thin patients it may be possible by palpation to feel a hardened area over the right lobe of the liver if it projects, as it frequently does in such cases, below the ribs.

Adhesions occurring between the stomach and colon owing to the mobility of the structures involved, may occasion few troublesome symptoms. If the pylorus should be concerned in the adhesion to the extent of interference with stomach drainage the usual signs of that condition would be manifest.

I have seen but one case of adhesion of the stomach to the colon, and in that instance the patient complained more of symptoms referable to the bowel than to the stomach. Operation in this instance, Case 6, revealed an adhesion between the greater curvature and the transverse colon which, when the stomach was empty, exercised sufficient traction on the colon to produce marked kinking.

The diagnosis of adhesions between the stomach and the pancreas presents many difficulties and may usually be only surmised by the existence of the general symptoms of such adhesions and the acceleration of pain and functional disturbance when the patient assumes the hands and knees or knee chest posture, which will increase the dragging as the stomach pulls on the fixed point.

In patients suspected of having perigastric adhesions the following considerations are of value:

1. The persistence of troublesome symptoms despite careful dietetic and hygienic regulations.
2. Previous history pointing to chronic ulcer of the stomach.
3. Evidence pointing to the occurrence of a localized peritonitis during the ulcerative period.
4. The fact that change of posture may greatly modify the pain. The hands and knees position increasing the distress in adhesions to the liver and pancreas and relieving that due to adhesion to the abdominal wall. The recumbent posture relieving that due to adhesion to the liver and pancreas and increasing it in adhesion to the abdominal wall.
5. Tight bandaging may ease the distressing symptoms, by relieving tension of the adherent surfaces.
6. The presence of a more or less fixed point of tenderness.
7. The detection of an area of increased resistance or induration.
8. The employment of artificial distension of the stomach for purposes of examination. This will in some cases reveal more or less distortion of the organ and may, in cases of adhesion of the liver, render the adherent area more accessible to palpation. For this purpose the method advocated by Mayo, who uses the stomach tube and the bulb of a Davidson syringe, inflating the stomach with air, will be found most satisfactory.
9. The symptoms and physical signs of gastric dilatation which, when due to perigastric adhesions, come on more suddenly and are accompanied by more pain than when occasioned by cicatrization.

The treatment of perigastric adhesions must be surgical if permanent relief is hoped for.

It is true that in many cases where the adherent area is large and the adhesions very dense, as is frequently the case when the liver and pancreas are involved, even surgery is unable to offer relief, but when the adhesion between the stomach and the liver is not too extensive it may be separated and the patient cured. Adhesions to the pancreas, though presenting many difficulties to operative interference, may, in some instances, be successfully separated. In those cases where the pylorus is adherent to the liver, gall bladder or abdominal wall, or where the adhesion exists between the stomach and the colon, brilliant results may be secured by surgical treatment.

As the condition of many of these patients is deplorable, an exploratory laparotomy should be made unless the symptoms point unmistakably to the existence of adhesions so extensive that their separation is out of the question. Operation in any of these cases will, of necessity, be often of an exploratory nature, as an exact diagnosis of the condition is usually impossible. If, when the abdomen is opened, the case is found to be inoperable, so far as the separation of the adhesions is concerned, some relief may be afforded by making a gastroenterostomy at the most dependent portion of the stomach. If it is decided that the adherent surfaces may be separated safely, this is done in the usual manner. If, during the separation of the adhesions, the wall of the stomach or the adherent hollow viscus has been weakened it must be infolded with Lembert sutures. If the separation leaves large raw surfaces the danger of adhesions again forming may be lessened by covering these areas with omentum or Cargile membrane. If dilatation of the stomach is present a gastroenterostomy should be made whether the adhesions are divided or not. Frequently the operation may present many difficulties and again it may be extremely simple. It has, in my experience, proven, on the whole, a very satisfactory procedure to patient and surgeon alike, in evidence of which statement I submit brief histories of seven cases.

These are all cases of perigastric adhesions due to chronic ulcer.

I have not included in this report those cases so frequently encountered of adhesion between the stomach and an inflamed gall bladder, where the gall-bladder symptoms predominate, except in one instance where the diagnosis of gallstones was made and an adhesion between the stomach and an otherwise healthy gall bladder was found.

Case 1.—E. J., a female, aged 32 years. She complained of very acute abdominal pain coming on soon after eating, which was frequently attended with vomiting. Coughing, sneezing, etc., were attended by the most excruciating pain. She had been constantly under treatment for one year, her ailment being diagnosed as dyspepsia, and was almost discouraged concerning her condition. Owing to the difficulty with which food was retained in the stomach, she was extremely emaciated. An examination of the abdomen revealed, on palpation, a tender indurated spot about one-half inch above and the same distance to the left of the umbilicus. This, together with the symptoms above enumerated, led to the diagnosis of an adhesion between the stomach and the abdominal wall, with, possibly, the formation of an abscess. The abdomen was opened and the adhesion existing between the anterior surface of the stomach and the abdominal wall was readily found.

This was separated without difficulty. No pus was present and the stomach wall at this point was found to be intact, the ulcer having apparently healed.

The ulcerated area, however, was folded in and retained by close suturing. The troublesome symptoms immediately disappeared and, fifteen months after operation, had not recurred. The patient rapidly regained her lost weight, and has since been in perfect health.

Case 2.—Male, aged 24. Had been treated three years for gradually increasing symptoms of digestive disturbance. These at first consisted of an uncomfortable sense of fulness after eating, which persisted for some time. Soon he was troubled with eructation of gas and fluid and then with frequent vomiting, which would appear an hour after eating. No history pointing unmistakably to ulcer of the stomach, but at one time had been quite sick for two weeks with symptoms of peritonitis. At the present time all symptoms are much aggravated. Soon after taking food he has severe pain in left side which seems more intense under right nipple. Vomiting soon follows and after emptying the stomach the distress gradually subsides. Has lost much weight and is very much concerned as to his condition. Is ravenously hungry, yet fears to eat. Examination reveals a very tender spot just to the right of the median line under free edge of ribs. At this point an obscure sense of increased resistance is made out by deep palpation Distension of the stomach with air (Mayo's method) brings on at once all the symptoms of pain and gastric distress and reveals the fact that the organ is much dilated, the lower border being two inches below the umbilicus.

The tender spot above referred to is now so sore that he can scarcely bear the slightest pressure on it. The history, together with the physical signs, led to the provisional diagnosis of adhesions existing between the pyloric end of the stomach and the liver and laparotomy was advised.

At the operation the pylorus was found firmly adherent to the right lobe of the liver, about one square inch of tissue being involved in the adhesion. Separation of the tissue was effected without difficulty and an anterior gastroenterostomy made at the most dependent part of the stomach.

The raw surface of the pylorus was covered with omentum. Relief from all troublesome symptoms was immediate and complete, the young man rapidly regaining his former weight and strength.

Case 3.—Male, aged 37. History pointing to existence of gastric ulcer six years before. For the last few months he had pain after eating, eructations of gas and finally vomiting, which now occurs several times daily. Has lost weight and strength and had to abandon his vocation, that of carpet laying, as the hands and knees posture assumed by him at his work greatly increased the pain. Examination revealed a very tender area exactly in the median line and just at the end of the sternum. Says that he vomits a few minutes after taking food, frequently ejecting all that he has eaten. Is very despondent and threatens suicide unless relieved. On taking the hands and knees position he gives every evidence of suffering intense pain, which is immediately relieved, but not abolished, when he lies on his back. Says that at times if he will lie down immediately after eating that the distressing symptoms may be very much lessened in severity and that he may not vomit at all. He refers the pain to the entire upper abdomen, and says that at its height it extends across from side to side just under the free edge of the ribs.

An exploratory laparotomy revealed extensive adhesions between the lesser curvature of the stomach and the under surface of the left lobe of the liver, involving a surface about two inches in diameter. These adhesions were separated with great difficulty and several vessels required ligation.

The large raw surfaces remaining, both on the stomach and the liver, were covered with Cargile membrane. Shock was pronounced and only overcome by most vigorous measures. To my great gratification readhesion of the denuded surfaces did not take place and recovery was rapid and absolute.

Case 4.—Young woman, aged 23. History of recurrent attacks of pain and soreness in upper abdomen for the last four years. Usually came on an hour or two after eating, and lasted from two or three hours to several days. Intervals between the attacks constantly growing shorter. Pain and sense of burning extending from right hypochondrium across to the left side and up to right shoulder blade. Vomiting occurred frequently, but not always present. Pressure of clothing could not be endured during the paroxysm. No history of hematemesis. Examination revealed exquisite tenderness over the gall bladder. The recurrent nature of the trouble, the character of the pain and the location of the tender area led to a diagnosis of gallstones.

Operation revealed an adhesion between the gall bladder and the pylorus, which, when separated, was seen to be due to a chronic gastric ulcer.

The gall bladder was apparently perfectly healthy, no stones could be felt in it or the ducts and the operation was concluded with the separation of the adhesion, and in folding the ulcerated area of the pylorus with Lembert sutures, as the stomach wall at this point appeared very thin.

Complete recovery rapidly ensued, thus adding unmistakable proof that the diagnosis of gall-bladder disease was a mistaken one.

Case 5.—Married woman, aged 21. History of chronic ulcer of the stomach four years previously. Lately has been suffering extreme pain after eating, which was located in the right hypochondrium and extending to the right chest. Vomiting was of frequent occurrence, coming on soon after eating and she was rapidly losing weight. The entire upper abdomen seemed tender to pressure and she had worn no corset or tight skirts for months.

As long as she remained in the recumbent position the pain and vomiting was less severe and some days she would suffer very little. Exercise greatly aggravated all symptoms.

Operation revealed adhesions between the lesser curvature, just above the pylorus and the liver. These adhesions were very firm and extended over an area half as large as the hand. Their division was quite difficult, and several times I thought I had better give up the attempt. It was finally accomplished and the large raw surfaces covered with omentum and Cargile membrane. The patient stood the operation well and made a good operative recovery, but the troublesome symptoms rapidly recurred, evidently because of the reformation of the adhesions. Refusing further operative interference, the case passed from observation.

A blunder was committed in this case by persisting in separating these wide and dense adhesions and by omitting to make a gastroenterostomy. Confronted again by such conditions, I should perform a gastroenterostomy and let the adhesions alone.

Case 6.—Married woman, aged 44. History pointing to ulcer of the stomach several years before. For the past three or four years has been troubled with vague and indefinite abdominal symptoms. These were apt to appear three or four hours after taking food and, to use her own description, "the right side would feel as if it were going to burst, while the left side felt flat." Pain extended at this time from the ribs to the groin on the right side and across the upper limits of the abdomen and was colicky in character. During the paroxysm distension of the abdomen was quite marked.

Vomiting might occur, but was usually absent. After a time varying from one to three hours, the symptoms would gradually subside, only to reappear following the next meal. Strict adherence to a liquid diet would often grant comparative freedom from the attacks for days at a time, but the taking of solids was certain to be followed by distress. Growing tired of the restricted diet, the patient asked if an operation would not give her relief.

An exploratory laparotomy disclosed an adhesion between the greater curvature of the stomach and the transverse colon which, when the stomach was empty, so drew on the latter as to produce a decided "kinking" of the gut which was sufficiently acute to interfere with the ready passage of its contents. This adhesion was easily separated and the surfaces participating in it were covered with omentum. Recovery was uneventful and has remained complete.

Case 7.—Male, aged 35. No definite history of ulcer. For several months had been suffering with symptoms of digestive disturbance manifested at first by eructations of gas and fluid and some abdominal tenderness. Soon began to vomit at irregular intervals and at the present time vomiting occurs several times daily and is accompanied by severe dragging pain over the upper abdomen. Is steadily losing weight and has had to entirely abandon business. Examination reveals much tenderness in right hypochondrium and an area of increased resistance above and to the right of the umbilicus. Distension of the stomach with air shows it to be much dilated and its movements may be seen through the thin abdominal wall.

All the symptoms are aggravated on his assuming the "hands and knees" position. Operation revealed adhesions between the pylorus and the liver, the pyloric end of the stomach being held firmly against the under surface of the liver while the stomach, enormously dilated, extended far below the umbilicus. The adhesion was separated with no especial difficulty and a gastroenterostomy was made. Much improvement followed the operation and, although restoration of function was not perfect, the patient having occasional attacks of pain, he had been able to resume active business.

A study of these cases would seem to warrant the following conclusions:

1. Perigastric adhesions as sequelæ of chronic ulcer of the stomach are not uncommon.
2. Their existence should be suspected and even positively diagnosed more frequently than has been the case.
3. In many such cases the relief afforded by the operation is absolute and may be secured in no other manner.
4. The operation is often an extremely simple one.
5. If the adhesion involves surfaces so extensive that its recurrence must be inevitable, relief may be best secured by a gastroenterostomy allowing the adhesions to remain.
6. The use of omental grafts or Cargile membrane is of value in preventing the readhesion of the separated surfaces.

THE SURGICAL CONCEPTION OF PYLORIC OBSTRUCTION.*

H. D. NILES, M.D.
SALT LAKE CITY.

Until within the past few years pyloric obstruction was regarded as due either to cancer so situated and so advanced as to render its removal impossible or excessively hazardous, or to a non-malignant pathology usually so obscure and so difficult to diagnose as to make any attempt at surgical interference uncertain and unjustifiable. Hence, surgeons were rarely encouraged to seriously consider operative procedures in stenosis of the pyloric orifice, and the victims of this condition were, with a few exceptions, permitted to die or to drift into chronic invalidism without a single rational effort being made to remove or correct the causative pathology.

It has been only within the past decade that the advances made in the surgery of the upper half of the abdomen and of the stomach in particular have inspired us with a new confidence, and given us a much clearer and more practical idea of this causative pathology, suggested a means of diagnosing it earlier, and indicated plainly the only measures we can reasonably rely on to prolong the lives of these patients or restore them to health.

Those who have kept in touch with these advances and thoughtfully compared their own clinical experience with that of the comparatively few workers in this field will, I believe, agree that the palliative, expectant treatment of the past must eventually give way to the more promising, prompt, rational measures suggested by the surgical conception of pyloric obstruction.

These experiences, as I interpret them, teach us that in at least 95 per cent. of all cases this obstruction is due either to cancer, ulcer or inflammatory adhesions, viz., to a pathology that at no time and under no conditions can be removed or corrected by any combination of medicinal or dietetic measures, but which in every instance at some stage of its progress affords an opportune time for removal or favorable modification by appropriate operative procedures.

We have learned, too, that the fears and apprehensions of excessive danger that so long retained our surgical endeavors in the upper half of the abdomen were greatly exaggerated and that the surgery of this part of the peritoneal cavity is not attended by unusual risks if we choose an opportune time for operating, while the morbid process is yet circumscribed and before the recuperative and reparative powers of the patient are exhausted. Indeed, it has been shown that the stomach will bear almost any kind of surgery with comparative safety to the patient if the operator is clean, the patient is in good condition, and the small intestines are not unnecessarily exposed or subjected to trauma.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Instructed by recent operating-room observations, we have modified many of our old ideas of pathology that were formed in the dead house. Not a few of these changes have an important surgical bearing. For example, it has been found that cancer of the pylorus, although situated in a part of the lymphatic system, is singularly slow to extend to nearby glands and, consequently, often offers really a better opportunity for complete removal than cancer of the uterus or breast. (I think it must be very rare, however, to find malignant disease so far advanced as to demand a complete gastrectomy, except the glandular involvement be such as to contraindicate any extensive operation.)

We know that gastric ulcer is rarely single and, while one may be able to diagnose and, in the course of the operation, to locate the particular ulcer that produces the symptoms and, perhaps, be tempted to excise it, it is safer to conclude that there may be one, two or three smaller ulcers so obscure as to escape detection or prevent excision. For this reason gastroenterostomy should usually be the preferred surgical treatment for gastric ulcers.

The fact that nearly three-fourths of the present mortality and sufferings from pyloric cancer and ulcer are due to the occlusion of the pyloric orifice must be regarded as a strong plea for the surgeon to relieve the obstructive symptoms, even when it is apparent that the perfect removal of the pathology is impossible or impracticable.

It seems highly probable that neither cancer, ulcer nor inflammatory adhesions are, as a rule, separate and distinct entities in this pathology, but are not infrequently associated as successive factors in the morbid process that results in organic stricture of the pylorus. It is certainly fair to presume that cancer in this region, as in the lip, cervix, nipple and elsewhere, finds its preferred, if not its essential, starting point in cicatricial tissue; and here this cicatricial tissue is most likely to be found about bands of adhesions and the healing of ulcers.

It has been customary in the past to regard blood dyscrasia as the chief cause of gastric ulcer; but I am inclined to believe that this view has been accepted more on account of its being the only available one than because of its sound pathologic basis. To me it seems more consistent to assume that the etiologic factors of gastric ulcer are not different from those of ulcer in other parts of the body, except as modified by local conditions, the anatomic relations and the physiologic functions of the stomach, and that in most instances the necrotic process is preceded by a local circulatory disturbance or lowered vitality of the part, and that in the stomach such degenerative changes are hastened and intensified by the well-known digestive effects of the gastric juice on devitalized tissue. The local circulatory disturbance, the locus minoris resistentiæ, is provided here whenever omental attachments or peritoneal adhesions drag, bind or compress any part of the stomach in such a manner as to impair or abolish its physiologic mobility or interfere with its normal blood supply.

That such omental attachments and peritoneal adhesions often occur with any nearby or remote intraperitoneal inflammation will not be questioned by any operator familiar with gall-bladder, appendiceal and tubal inflammations, and is able to recall how almost invariably the omentum is involved and peritoneal adhesions formed.

Just what proportion of cancers are preceded by gastric ulcers and just what proportion of ulcers are caused by peritoneal bands of adhesions or omental attachments, no one as yet may presume to decide; but the fact that there is a very intimate relationship between these causative factors, with an inflammatory lesion at the one extreme and malignant disease at the other, should be kept in mind in taking the history, in making the differential diagnoses and in deciding on the treatment of each case.

I am quite sure that in a number of instances I have been able from the history to trace the successive steps of the pathologic process from an old inflammatory lesion (appendiceal, gall bladder or tubal) to a cancer of the pylorus or to a gastric ulcer; and within the past two months I have operated on two cases where such conclusions were suggested by the history and afterwards verified on the operating table. In one case, the obstruction was due to cicatricial contraction following an ulcer. Some years before, the patient had suffered from a well-marked attack of appendicitis lasting nine weeks. After a recurrent attack symptoms of pyloric obstruction appeared which in time became so aggravated as to lead him to seek surgical aid. The appendiceal mass, the omental attachment, the ulcer, etc., were demonstrated in the course of the operation. The history of the second case was typical of chronic ulcer with partial occlusion for a period of three years. Since November, 1902, the symptoms had rapidly become more serious and indicative of malignancy. The operation demonstrated the existence of a cancer of the pylorus freely movable and with but little glandular involvement. In this connection is it not logical to believe that the hemorrhage that so often occurs a number of days after gall-bladder operations may be due to ulceration from the above causes rather than from some obscure blood dyscrasia?

This explanation of the etiology of gastric ulcer, which I have submitted for your consideration, not only appears to harmonize with the general teachings of pathology, our operating-room findings and clinical experience, but is apparently supported by the results of a series of experiments on animals which I have recently undertaken, the details of which I hope to make the subject of a future paper.

This, in brief, is an outline of the pathology we may be facing whenever in our consulting room or at the bedside we are confronted by a patient suffering from any serious chronic disease of the stomach. And since the life and health of the possessors of this pathology depend as much on our promptness in recognizing it as on our judgment and skill in correcting it, the first and most important step toward the discharge of our duty to these patients is to hold ourselves prepared and on the alert to detect any early warning symptoms, and to spare no pains in our efforts to look beyond the symptoms to the morbid conditions that produce them.

Undoubtedly in the past we all have been inclined to permit the early stages of organic stricture of the pylorus to escape our observation. So long as an early and positive diagnosis served only to give an early and positive assurance of impending death or a life of invalidism, neither physicians nor patients were enthusiastic in securing convincing clinical evidence. The gathering of testimony that can only serve to deprive the patient of the last ray of hope seldom engages the best efforts of the medical profession.

But now as surgeons are beginning to demonstrate to physicians that we have good substantial grounds for our faith in the efficiency of surgery if employed early, we may reasonably hope to win that which at the present time we most need—the confidence of the patient and the co-operation of his first counselor, the internist.

GENERAL RULES FOR DIAGNOSIS.

Time will not permit our dwelling on the symptomatology of pyloric obstruction, and I shall only venture to call your attention to a few general rules that I have found helpful to me in systematizing my examinations and in aiding me to reach an early decision.

First.—Suspect all cases of serious chronic disease of the stomach to be suffering from pyloric obstruction and subject each to a rigid investigation unless the symptoms are plainly due to other causes.

Second.—Since the history is always our earliest and often our most significant and sometimes our only clue, it should be reviewed and studied in every case with scrupulous care, due attention being given to the age and habits of the patient, date of commencement of present illness, location and character of pain, loss of weight, vomiting of blood or undigested food, the length of time after eating the vomiting and pain occur, attaching especial weight to any history of previous attacks of abdominal pain or distress that might indicate a local or general peritonitis.

Third.—Note the appearance of the patient, whether cachectic, jaundiced, anemic or well nourished.

Fourth.—Locate the point of greatest tenderness, determine presence or absence of tumor, note contour of abdomen, and, most important of all, mark out the boundaries of the stomach when distended, for marked dilatation is almost pathognomonic of obstruction.

Fifth.—Examination of the stomach contents after a test meal, including the test for hydrochloric acid, may furnish very significant but never positive evidence as to the malignancy or non-malignancy.

Sixth.—The presence of a tumor with or without glandular enlargements is strongly suggestive but not absolute proof of malignancy.

Seventh.—Remember that in spite of the most painstaking investigation a certain proportion of cases will remain obscure if we employ only the ordinary means of diagnosis. In such cases, when malignant disease is suspected, or without such suspicion, if the obstructive symptoms be marked, or the patient is greatly distressed, or his general health and strength are being surely undermined, we have no right to postpone an exploratory incision. For, at the hands of an experienced operator, this is a safe procedure and always gives positive information that is obtainable in no other way. (I am convinced that each year many lives are sacrificed because of our hesitancy or delay in employing this important diagnostic measure.) The fact that pyloric obstruction is always a surgical disease does not mean that all cases are to be invariably subjected to operation. The same conditions that demand an exploratory incision usually require the surgical treatment, for with such symptoms, if there be no organic stricture, there is likely to be angulation of the pylorus due to adhesions, or spasmodic stricture due to ulcer, and neither are susceptible to any non-surgical treatment.

OBJECTS OF SURGICAL TREATMENT.

The modern surgical treatment of pyloric obstruction includes two objects:

First.—The establishing of a communication between the stomach and the duodenum or the jejunum.

Second.—The removal of the causative pathology.

The first is imperative in every instance, and under favorable conditions is attended by a moderate risk. The second is always desirable, but not always advisable; for the character and extent of the pathology together with the condition of the patient may not justify us in attempting the second object.

Many ingenious operations have been proposed and practiced for the accomplishment of these two objects. I am impressed, however, that it is a mistake to enter the operating room with the mind over-burdened and perhaps confused with the details of many complicated procedures, and I am sure that better results would be obtained if we, especially those of us who operate infrequently, would strive to perfect our skill and dexterity in the use of a few of the simplest measures that promise to accomplish the objects desired.

SOURCES OF ERROR.

Four other sources of error deserve mention:

First.—Attempting to do too much. The welfare of the patient as well as the best interests of surgery sometimes contraindicate an ideal operation. After doing a gastroenterostomy, it may be even advisable under certain conditions to postpone for a time the removal or correction of the pathology.

Second.—Selecting an operation that requires too long a time for its performance. Very few of these patients reach the operating table in condition to bear a two or three hour operation.

Third.—Forgetting that the first part of the duodenum is but two or three inches long, and one-third of this is only partially covered with peritoneum and a portion of the remainder is usually excised with the disease. Hence, to attach the esophagus or greatly dilated stomach to such a short immovable duodenum might in many instances produce undue tension, which here would be a dangerous violation of a well-known surgical principle. Unquestionably when in doubt the safer course would be to do a gastrojejunostomy.

Fourth.—While in the latter operation it is immaterial whether the anterior or posterior wall of the stomach be entered, it is most essential that the lowest point of the stomach be selected, and that we especially guard against the possibility of any kinking of the jejunum by appropriate measures, even to the doing of a supplementary enteroanastomotic if necessary.

A gastroenterostomy with the Murphy button and a pylorectomy or partial excision of the stomach after the method described by Dr. W. J. Mayo, are procedures that appeal to me on account of their simplicity, ease of execution, short time required and general effectiveness, and in my limited experience they have proven satisfactory. Those more dextrous in intestinal suturing and general operative skill might do well to select other methods or perhaps do away with any mechanical device like the Murphy button.

What, at the present time, needs to engage our thoughtful attention more than the multiplying of operative procedures, is a study of these morbid processes in life as they are revealed to us on the operating table, that we may acquire a quicker perception of the symptoms they produce, and become better prepared to judge when and when not to attempt the removal or correction of the pathology. We need, too, perhaps most of all, to secure the intelligent co-operation of the internists, for until they appreciate that pyloric obstruction is a surgical condition and one that can not be always even diagnosed except by an exploratory incision, and that can never be hopefully treated except by operation—until the internists not only accept these views in theory, but adopt them in practice, the *dernier resort* operation will continue to be the rule and the timely operation the exception, and the greatest benefits to be derived from pyloric surgery will not be realized.

REASONS FOR SURGICAL TREATMENT.

Our reasons for believing that the rational treatment of pyloric obstruction should be based exclusively on the surgical conception of the conditions, may be briefly summarized as follows:

First.—In 95 per cent. of all cases the pathology is an organic stricture of malignant or benign origin. It is certainly unreasonable to hope that stricture of this or any other part of the alimentary canal can be overcome except by mechanical means; and it is equally inconsistent to assume that pyloric cancer will yield to palliative treatment or to any other measures that are known to be of no value in the treatment of cancer in other parts of the body.

Second.—Pathology in this region can be reached, exposed and treated quite as conveniently as in other parts of the peritoneal cavity.

Third.—With an early diagnosis and the elimination of the "too late operation," pyloric surgery ought not to be attended by unusual risks, and should promise as good results as surgery done for equally grave conditions in other parts of the peritoneal cavity.

Fourth.—If the ordinary diagnostic measures are not sufficient to enable us to always reach a prompt decision, we know that here a small exploratory incision is a simple, safe procedure, which gives the patient but little discomfort and always affords the surgeon positive information as to the exact conditions.

Fifth.—When life and health are threatened by any intraperitoneal disease, benign or malignant, the timely removal or correction of the causative pathology by mechanical means is a rational procedure of proven value which we should always thoughtfully consider before we permit ourselves to regard the condition hopeless, or subject our patients to the chances of any empiric treatment.

The discussion on the papers of Drs. Knott, Niles and Ochsner will follow the paper of Dr. Ochsner in a subsequent issue.

THE SERUM DIAGNOSIS OF TUBERCULOSIS.

L. M. LOEB, M.D.
FELLOW IN PATHOLOGY.
CHICAGO.
(From the Pathological Laboratory of Rush Medical College.)

In numerous journals at short intervals beginning in April, 1898, the Lyonese observers, Arloing and Courmont, have announced the discovery of a means for the diagnosis of early tuberculosis more certain and less harmful than any hitherto known. This naturally attracted great attention at once, although on account of the many difficulties in experimentation and control of results relatively few repeated the original measures. Many means and ways for the diagnosis of incipient tuberculosis have been suggested of late years, but all of them are either harmful or insufficient. By "incipient" tuberculosis is meant that period of the disease in which Koch's bacillus can not be clinically detected in the lesion it produces or in the products thereof.

A few of the methods devised, with the objections to them, are the following:

1. The tuberculin test and its modifications by Koch and others. In this test, filtered or centrifugalized cultures of tubercle bacilli in glycerin bouillon are injected into the patient, and on the following day a febrile reaction occurs in case tuberculosis exists. Sometimes dead tubercle bacilli are used; at other times attempts are made to remove the bacilli from the living cultures by the centrifuge or filter. The chief objections to this method are:

a. It can not be used (according to Koch and his school) in cases in which the temperature rises above 100 F., because the febrile reaction is not sufficiently evident and because harmful results are frequent in these cases.

b. The reaction occurs in latent and practically healed cases, and is said by many, both in these as well as in other mild cases, frequently to cause exacerbations of the disease when not acutely active. It is said very often to change chronic benign forms to acute and virulent ones.

c. Instances have been reported of the production of localized and later of general tuberculosis following the inoculation with tuberculin. Even in the cases of Koch's latest product, "Neutuberculin,"[1] virulent living tubercle bacilli were found in the fluid by Thellung,[2] and rabbits and guinea-pigs were infected.

d. Not all cases react, in which, according to Koch, the use of tuberculin is indicated. It is important to note, too, that the reaction may occur in healed cases and thus may create the impression that the patient is suffering from tuberculosis when the disease in reality has been overcome.[3]

2. Still more unsatisfactory than the use of tuberculin are substitutes for it; of these there have been many. Originally human and animal blood sera were advocated; later artificial blood sera (in which only the inorganic elements of the blood were used), and finally a simple physiologic solution of sodium chlorid.[4]

All of these later methods have been proven less reliable than the use of tuberculin and are subject to all of the same criticisms except the actual introduction of tubercle bacilli. Although apparently harmless, they have also been accused of stimulating latent foci to activity and of causing chronic cases to pursue a more acute course. Their use has, therefore, been generally abandoned.

3. Absolutely harmless, but extremely limited in its field of application, is the injection of animals with supposedly tuberculous products. The method is, however, slow in results; it is not certain and can not always be employed, because necessary materials can not be obtained. In cases where mixed infections have occurred this means can not be used at all, as the animals may die before any evidence of tuberculosis manifests itself.

4. Sometimes tubercle bacilli undoubtedly occur in the sputum and other products, but can not be discovered on account of their rarity. In such cases, e. g., in suspected pulmonary, intestinal or genitourinary tuberculosis, the growth of tubercle bacilli from the products of the processes they induce would be an ideal method of diagnosis, if practicable. Many have devised means of hastening the development of the bacilli under such conditions. The technic, however, is extremely difficult, and the results, up to the present time, have been unsatisfactory. No attempt will be made here to enumerate the endless varieties of culture media suggested for this purpose. It will be sufficient to mention the most promising, that of Hesse,[5] endorsed by some,[6-7] condemned by others.[8]

The great difficulties associated with cultural methods can be appreciated only by one who has attempted to isolate tubercle bacilli from or even to find them in a mixed culture. I have carried out in twenty cases the measures recommended by Hesse and Jochmann. In five the increase in numbers of tubercle bacilli was considerable, but the number in the original smear preparations was also great. The organisms never seem to multiply greatly unless a large number is used for the first implantation. Up to the present time but few if any cases have been reported in which the diagnosis has been made by the use of cultural methods; and my experience does not create confidence in its practicability.

5. Little can be said at present regarding the merits and demerits of "cytodiagnosis," i. e., the diagnosis of the nature of effusions by the determination of the cells therein contained. Though considerable emphasis has been laid on it by certain French clinicians, it has not been extensively used; many unsatisfactory results have been published and its field of usefulness must necessarily be limited to the study of exudates.*

THE AGGLUTINATION REACTION.

The method of Arloing and Courmont has been claimed to be fully as satisfactory as any of the above and free from any dangers. Nor has its application any limitations—effusions of blood can be used with equal readiness and practically the same results. The only things required for its execution are proper homogeneous cultures of tubercle bacilli and their mixture with blood or other serum, as by the Gruber-Widal method for the diagnosis of typhoid fever.

TECHNIC.[9]

a. Preparation of Cultures.—In the first place, cultures of human tubercle bacilli are grown on potatoes. These potatoes should be of such a character that they do not turn brown on boiling and should readily give up starch granules from the cut surface. They are boiled, put into potato tubes, in the bulb of which is placed enough of a 6 per cent. solution of glycerin in water to touch the lower edge of the potato. They are then put in the autoclave at 111 to 115 C. for the shortest possible time required to render them sterile (about 45 minutes). "Inoculate one of the surfaces of the potato and put the tube in an incubator at 38 to 39 and inclining it at such an angle that the inoculated surface points up and the glycerized water bathes the lower extremity of the slice." Every other day the tube should be tipped so that the colonies are gently immersed in the fluid. As a result of this procedure a luxuriant growth is obtained, which differs from the ordinary growth in being soft and easily completely broken up by stirring in a small mortar or touching with a glass rod. From these growths subcultures are made into the bouillon which is used for diagnosis. To give the best results, this bouillon should be made from beef or veal with 1 per cent. of peptone and 6 per cent. of glycerin. In these proportions the bouillon, while not producing the most luxuriant cultures, furnishes those with the greatest agglutinability.

The object of Arloing and Courmont in devising this elaborate and difficult technic, was to obtain cultures in which the tubercle bacilli were distinct, unclumped and motile. The potatoes are used in the designated way to accustom the organism to liquid surroundings, as well as to obtain soft and easily separable growths. The bacilli when transplanted are preserved distinct, while multiplying in the bouillon, by daily agitation. In this manner we obtain "homogeneous" cultures. An "homogeneous" culture is one which is more or less cloudy or turbid, contains very little or no sediment and in which the bacilli are found isolated, or at any rate not in large clumps. Usually the presence of some small clumps can not be avoided. It is advised to use for the bouillon subcultures cylindrical, i. e., flat-bottomed test tubes, because in these the cultures can be more efficiently agitated.

As a result of this technic Arloing[9] describes the organism as motile, isolated, straight or slightly curved, often granular, and as a little larger than the bacilli in tissues and as acid proof. Some observers have stated that the degree of motility is equal to that of the *Bacillus typhosus*, but usually the motion is said to be slow, but distinctly progressive. However strange the motility of the tubercle bacillus may seem, some who have worked independently of the Lyon school and with other culture media have made similar observations.[10] Branching forms have been described a few times as a consequence of this method of growth. In my experience they have been especially frequent.

Buard and others[11] state that it is preferable to transfer growths from bouillon to bouillon. After a year of such transplantation Buard believes to have found that (*a*) the cultures grow more rapidly; (*b*) the bacilli are more motile, i. e., the motility is proportionate to the rapidity of growth; (*c*) clumps are less numerous, and (*d*) the bacilli are longer and more slender. The same author prefers the use of carrots to that of potatoes for the initial growth. The method of transference from bouillon to bouillon has proven unsatisfactory in my hands, inasmuch as it has never been possible to grow many bacilli beyond the fourth generation. Nor has it at any time been possible to find more than an active Brownian motion in the hanging-drop preparation. Koch[2] at one time expressed doubts as to the identity of the bacillus described by Arloing and Courmont with his.

b. Use and Preservation of the Cultures.—The bouillon culture should be used for the reaction between the ninth and the fifteenth day of its growth, preferably not later than the 12th. Previous to this it should be shaken thoroughly at least once, better twice, daily. Before the eighth day not enough bacilli are present. After the fifteenth day agglutination with serum is lessened, while on the other hand there is some danger of autoagglutination, i. e., clumping occurs in the culture without the addition of any substance and in spite of most careful agitation.* To preserve the agglutinative power intact, several methods have been devised and are necessary, because the amount of labor required for a single reaction would be enormous if the fluid could not be preserved "homogeneous" for some time. After a culture has proven efficient by testing with a known serum, it may be kept in a good condition for two weeks by any of the following methods: 1. One part formalin to 400 to 600 culture. 2. Carbolic acid in the same proportion. 3. Culture placed in a cold, dark place, as in an icebox. Preferably method 1 or 2 should be combined with 3.[12] More or less precipitation always occurs on standing, and only the supernatant fluid should be used for the tests.

---

* *Cytodiagnosis* has been extensively studied in France by Widal, Sicard, Ravaut and many others. A predominance of lymphocytes in the exudate and an absence of endothelial cells "is the formula for an idiopathic, i. e., tuberculous pleurisy." The new membrane is said to prevent the desquamation of endothelial cells. In other forms of inflammation of serous membranes, endothelial cells and polymorphonocular leucocytes predominate; lymphocytes are relatively few (Widal and Ravaut: Gaz. des Hôpitaux, vol. xxii, No. 30). Arloing and Courmont and their school have used this method as one of their controls in the determination of results and find it valuable.

* *This corresponds* in some respects to the occurrence of autoagglutination in older typhoid cultures as described by Savage, Jour. of Path. and Bact., 1901, vol. vii, pp. 388-399.

c. The Reaction.—To obtain the reaction a perfectly clear serum—blood serum, or inflammatory or simple effusion—is mixed with the culture fluid in varying proportions from 1:3 to 1:50. Preferably a 2 c.cm. test tube is used in which 1, 2, 3, or 4 drops of serum are mixed with bouillon in amounts sufficient to produce the proper ratios. The tubes are inclined at an angle of 45 degrees and allowed to stand in an incubator for from 2 to 6 hours.[13] They are examined at intervals, both with the unaided eye and under the microscope. To the unaided eye the fluid, providing the reaction be positive, should appear less turbid than the control, while a flocculent precipitate appears on the bottom or sides of the tube. The tubes should be examined in a bright light against a dark background.[14] Examined in the hanging-drop preparation the bacilli should appear clumped; not so in the control. Many and varying opinions have been expressed as to the relative merits of the microscopic and macroscopic tests, some holding the one,[14] some the other[15] of prime importance. Both should be used; in the large majority of cases the results are the same; in a few differences are found.

Several difficulties and sources of error present themselves with especial frequency in judging whether or not a positive reaction has taken place. The culture may not have been sufficiently turbid on account of the deficient growth of the bacteria to enable one to decide very readily whether it has cleared to a marked degree in the given time. The reaction can not compare in its sharpness, as a rule, to that seen in the Gruber-Widal reaction. In the examination of the sediment larger clumps must be distinguished from the light flocculent precipitate produced by the reaction, for often, in spite of the most painstaking technic, larger masses of tubercle bacilli may appear in the fluid. Moreover, foreign bodies, such as cotton and dust, may occur. When perfectly fresh serous fluids are used, especially inflammatory exudates of high specific gravity, the precipitation of some fibrin is of very frequent occurrence and must not be confused with clumps of tubercle bacilli. In the microscopic examination, similar precautions must be taken. Sometimes it is impossible to say whether one sees bacilli or extraneous matter. In such cases it is advisable to fix and stain the hanging-drop. By this procedure one is often surprised at finding very few bacilli in a drop, which, in the unstained specimen, appeared to be loaded with them.

MODIFICATIONS IN THE TECHNIC.

The most important modifications in the technic as originally suggested are those of E. Romberg[16] and Robert Koch. Romberg's medium is prepared by the action of 1.5 per cent. NaOH on dried and macerated tubercle bacilli, which are then neutralized by acetic acid. Finally an emulsion is made, which is used for the reaction. This becomes clear when mixed with a serum in the course of 40 to 44 hours. The changes occurring in the second half of the second day are of no diagnostic significance. The microscopic test is of less value than the macroscopic. In the hanging drop small bodies appear in active motion for hours unless an agglutinating serum is added.

Koch's method is essentially the same. Any culture derived from a liquid medium is dried on filter paper, rubbed up in a mortar and diluted 100 times with n/50 NaOH. It is then centrifugalized and the precipitate removed, rendered less alkaline by weak hydrochloric acid and finally diluted with 0.5 per cent. aqueous carbolic acid and 0.85 per cent. NaCl until the original culture has been diluted 3,000 times. The fluid so prepared, it is claimed, is more delicate in its reactions, more easily made and keeps better than the Arloing and Courmont. It is an opalescent liquid and becomes perfectly clear with a positive reaction. Koch recommends cupping as a means of obtaining serum; Arloing and Courmont prefer removal of blood by venipuncture and separation of the corpuscles by centrifugation or clotting.

Romberg's method has been little used; that of Koch seems to have no special advantages[17] and offers greater opportunities for infection of the worker.

RESULTS.

In the newborn there is no reaction in any dilution, nor is there in the very young who have been free from disease.[11,18] The serum of guinea-pigs, rabbits and calves in good health never reacts in as high proportion as one part of serum to five of culture. That of dogs, goats and oxen normally reacts, in this dilution, often higher.[19] From these observations it has been concluded that animals, which are resistant to tuberculosis, acquire sera exhibiting the highest agglutinative powers. The serum of healthy adults may or may not cause agglutination; also that of clinically non-tuberculous patients. In most of these on whom autopsies have been performed latent or healed tuberculous foci have been detected, often, however, only after most painstaking search. The best reactions occur in those cases which are most resistant. The acute cases and those in whom marked cachexia has developed frequently fail to react. Rothamel,[20] whose especial study was the sero-reaction in twenty advanced cases of tuberculosis, obtained no reaction whatever in 30 per cent. of the cases, and in 25 per cent. only at 1:5, which is not better than that frequently obtained in the non-tuberculous subject. This agrees quite closely with the results of Arloing and Courmont and others.[21] On the other hand, those cases in which the symptoms are mild or nil and which progress to rapid recovery, agglutinate the homogeneous cultures in high ratios, i. e., at 1:15-50. The agglutinative power increases with the tendency to recover. The cases which succumb without a struggle do not produce an antitoxin (?) and their serum has no agglutinative properties. Courmont compares this phenomenon to that observed by Tchistowitch and Epiphanoff[22] and himself[23] in cases of typhoid fever. Courmont found that in this disease the Gruber-Widal reaction in mild or moderate cases occurred on the average in dilutions of 1:90. The maximum agglutinative power was never simultaneous with the maximum of symptoms, but almost always appeared at the time of defervescence or even in the post-febrile period. On the other hand, in the more severe cases, the dilution could not, as a rule, be so high; the maximum fluctuated from time to time and became decidedly less just before death. This author even believed that he was justified in drawing some conclusions from these observations regarding the prognosis and the probability of relapse. He believes that the agglutinating reaction in typhoid fever is inversely proportionate to the severity of the case.

On the whole, the reactions of sera derived from effusions into the serous cavities prove nearly as satisfactory for tests as blood serum.[24] Non-tuberculous effusions in tuberculous patients are said not to develop agglutinins, while those originating from tuberculous processes possess as great or even greater powers than the blood serum of the same patient. The results of Romber,[16,18] Donath,[25] Kazarinoff,[26] Mongour and

Buard[11,15,27] Dubard,[28] Rothamel,[20] Clement,[29] Rumpf and Guinard,[17] Ivanov,[30] Hawthorn[14] and Bendix[31] agree in all essentials with those of Arloing and Courmont, although not all draw the same conclusions as to the value of the test for diagnostic purposes. It will, therefore, be sufficient to illustrate the nature of the results by a single series of cases reported by Arloing and Courmont. Results under 1:5 or occurring after the allotted time are considered negative.

362 CASES IN WHICH BLOOD SERUM WAS EMPLOYED.

	Pos.	Neg.
a. Clinically tuberculous (191)......	168 (87.9%)	23 (12.1%)
b. Clinically non-tuberculous (130)..	45 (34.6%)	85 (65.4%)
c. Healthy individuals (41)..........	11 (26.8%)	30 (73.2%)

CASES IN WHICH SEROUS EFFUSIONS WERE USED.

	Pos.	Neg.
a. Tuberc. pleuritic effusions (31)......................	23	8
b. Pleur. of doubtful origin (16)......................	13	3
c. Hydrothorax (non-tuberc.) (11)......................	0	11
d. Tuberculous ascites (13)......................	11	2
e. Non-tuberc. ascites (20)......................	0	20
f. Tubercul. meningitis......................	..	..

In children all negative. In adults two positive.

Many hundreds of cases have been reported by various observers, and most of them have tables of a nature similar to the above. It may be of interest to compare with these the results of the use of tuberculin as reported by Max Beck. His extensive work with patients of all varieties should give us some notion of the prevalence of undiagnosed tuberculosis. Altogether 2,508 persons were given tuberculin. Of these 1,525, or 60.9 per cent. reacted positively. Of these, however, only 371 gave any clinical evidence of tuberculosis, while the rest, 1,154, or 46 per cent. of all tested, clinically were free. Judging from the results of extensive comparisons between the reactions to tuberculin and postmortem examinations by E. France (quoted by Koch) and numerous veterinarians, little doubt exists that most or all of this 46 per cent. had latent or healed tuberculosis. This figure is not far from that obtained by most of those who have used the serum reaction for the clinically unaffected. (Romberg's reactions for the "non-tuberculous" were 62.7 per cent.) These facts give us a reason why so many apparently normal adults respond to the serum test.

Romberg calls attention to the work of Nägeli,[32] whose study of 500 bodies with a view to discovering tuberculous lesions gives us material for comparison. A single series of cases is here cited:

Age.	Active Latent. Per Cent.	Doubtful. Per Cent.	Inactive Latent. Per Cent.	Total. Per Cent.
18-30	62.0	5.0	33.0	67.0
30-40	42.0	16.0	42.0	58.0
40-50	29.0	18.0	53.0	47.0
50-60	25.0	17.5	57.5	42.5
60-70	27.0	17.0	56.0	44.0
70-80	24.0	21.0	55.0	45.0

The total is made up of those cases which are latent but not healed and those which are doubtful, i. e., those in which it is not possible to judge from the anatomical findings whether or not the process had terminated. Romberg believes that all of these cases react to the serum test. (The above table does not include any but latent cases.) Evidently not all tuberculous individuals react, inasmuch as Nägeli finds some evidence of tuberculosis in practically every adult body (98 per cent.). In children, on the contrary, Nägeli found in 88 necropsies only 15 with tuberculous lesions; most of these were over 14 years of age. In 11 cases this disease caused death. The rarity of a positive serum reaction in a child, therefore, may be interpreted as being due to the scarcity of benign forms of tuberculosis in these years.

A very interesting and important observation in regard to the agglutination of tubercle bacilli was made by Arloing.[33] He found that injection of certain chemicals (other than tuberculin) produced in animals agglutinating sera. Such chemicals are eucalyptol, guaiacol, creosote and mercuric chlorid. The serum reaction produced by these is not so powerful as that produced by the injection of tuberculin, but agglutination occurs in the average dilution of 1:10. Dubard[34] obtained similar results. Not only did the latter find that sera produce precipitation of bacilli, but that even aqueous extracts of tuberculous tissue, of healthy livers and solutions of various chemicals cause sedimentation.[35]

EFFECTS OF AGGLUTINATION ON THE BACILLI.

These have been studied at length by F. Arloing.[36] He sums up the changes in the bacilli produced by the agglutination as follows:

1. There is no change in the morphology or staining characteristics.

2. Contact with agglutinating sera for 5, 10 or 24 hours does not produce bacteriolysis or bacterial death.

3. On the contrary, after 5 to 10 hours of contact the growth in liquid media is considerably improved.

In addition, the motility is found to be decreased or absent and the bacilli lie in clumps of various dimensions.

These statements are not in accord with those of Courmont,[21c,g] who states specifically that tuberculous effusions are decidedly bactericidal. For my part, I have been unable to obtain growths from such bacilli, but experimental inoculation into animals invariably produced tuberculosis. It is of considerable significance that human tubercle bacilli are agglutinated by the serum of all varieties of animal tuberculosis. The converse is no less true. Not only that, but the same effects have been noted by Koch[2] in similar preparations of many other acid-proof bacilli, which are non-pathogenic for man and other mammalia, such as the butter-bacillus (Rabinowitch), the grass bacilli of Korn, the timothy bacillus, the bacillus of fish tuberculosis, etc.

PERSONAL OBSERVATIONS.

My own experiments are limited to 52 cases, in some of which the tests were repeated from time to time, and in which bouillon suspensions of various ages were used.* As a rule, if the suspension was not more than 18 days old no difference in the results was noted. The reactions did not vary after some time had elapsed except in a few instances, which shall be noted below. In 16 cases the blood serum was employed, in 36 pathologic effusions into serous cavities. The tests were as carefully controlled as possible by clinical data, in some cases by tuberculin and in many by injections of effusions into guinea-pigs. In every case a control tube was used, which was compared with those in which sera were being tested. Dilutions varying from 1:15 to 1:20 were used in almost every experiment. In the following tables the positive reactions are given in their greatest, the negative in the least dilution tested.

In brief, the following results were obtained:

BLOOD SERA (16).

Obtained from children suffering from scarlet fever, but otherwise healthy. Cases 4, 5, 6, 8 (14), 12, 16. All negative at 4:15.

Adults suffering from scarlet fever, otherwise apparently healthy. Case 11.—Young man; neg. at 4:15. Case 10.—Positive at 1:15. Case 15.—Positive at 1:20.

In none of these cases was there any clinical tuberculosis.

---

* The original culture of tubercle bacilli used in these experiments was kindly sent to the laboratory of Rush Medical College by Dr. Trudeau of Saranac Lake, N. Y. The culture was isolated directly from the sputum of a case of acute phthisis by Hesse's method. It had been grown on artificial media for about six months and had never been passed through animals.

Blood from case of puerperal hemorrhage. Case 20.—Neg. at 1:5.
Man. Case 22.—Healthy; neg. at 1:5.
Man. Case 47.—Healthy; neg. at 4:15.
Dog. Case 20.—Healthy; pos. at 1:5.
Case of organic heart disease. Case 26.—Neg. at 4:15. Clinically and at autopsy no active tuberculosis.
Typhoid fever and miliary tuberculosis in young negress; positive Gruber-Widal reaction. Fever two months. Progressive lung changes. Death three months from onset. Pos. at 1:15.
Miliary tuberculosis (autopsy). Case 21.—Positive feebly at 1:10 two to three weeks before death.

PLEURAL EFFUSIONS.

1. Probably or positively tuberculous.
    Case 1.—Pos. at 1:10 in 2 hours.
    Case 2.—Pos. at 1:10 in 4 hours.
    Pos. at 1:20 in 16 hours.
    Case 27.—Pos. at 2:15 in 12 hours.
    Inoculated g.-pig tuberculous.
    Case 32.—Pos. at 1:5 in 12 hours. Greater dilutions negative. Well nourished; one previous attack.
    Case 51.—Pos. at 2:15.
    Case 38.—Pos. at 2:15 up to two days before death; tuberculosis at autopsy.
    Case 31.—Neg. at 1:5. Repeated attacks; emaciation, etc. No bacilli in sputum.
    Case 53.—Neg. at 4:15.
    Case 55.—Neg. at 3:15.
2. Non-tuberculous.
    Case 3.—Nephritis. Neg. in 10 hours.
    Case 18.—Post-pneumonic empyema. Neg. at 1:5. Pus was allowed to settle for three days; then formalinized at 1:20 and allowed to stand one day.
    Case 24.—Organic heart disease. Neg.
    Case 28.—Organic heart disease. Neg.
    Case 46.—Acute pleurisy following exposure; first attack. Neg. at 1:5.
    Case 33.—Empyema pus, post-pneumonic. Pos. at 2:15 in 12 hours; subjected to same conditions as Case 18.
    Case 48.—Pyemia. Pos. at 1:15. General inflammatory conditions: pericordium, pleura, etc. *Staphyl. pyog. aureus* isolated *from blood.*

ABDOMINAL EFFUSIONS.

1. Tuberculous.
    Case 36 (42).—Good response to tuberculin. Pos. at 1:7½.
    Case 37 (44).—Pos. at 2:15, 2 months before death. Pos. at 1:5, 2 weeks before death. No good response to tuberculin. Pig died in 45 days of miliary tuberculosis.
    Case 40.—Neg. at 1:5. Hyperplastic tuberculosis of lymph glands, tuberculous peritonitis, etc. *Necropsy.* Fluid obtained on day before death.
2. *Non-tuberculous.*
    Case 9 (13).—Cirrhosis. Neg. at 1:5; second test feebly pos. at 1:5.
    Case 23.—Cirrhosis. Neg. at 3:15. (? at 4:15.)
    Case 54.—Nephritis. Neg. at 1:5.
    Case 39.—Splenic anemia. Neg. at 1:5.
    Case 56. Probable cirrhosis. Neg. at 1:5.
    Case 34.—Typical cirrhosis. Pos. at 1:15.
    Case 50.—Cirrhosis. Pos. at 1:7½ macroscop. Neg. microscopically.
    Case 49.—Cirrhosis. Pos. at 1:5; neg. at 1:7½.

KNEE-JOINT EFFUSIONS.

1. Tuberculous.
    Case 7.—Pos. at 1:20 in 4 hours.
    Case 30.—Pos. at 1:5; Neg. at 1:7½.
2. Non-tuberculous.
    Case 19.—Gonorrheal arthritis. Neg. at 1:5.
    Case 43 (46b).—Multiple arthritis, probably rheumatic. Neg. at 1:5.

MENINGEAL FLUIDS (ALL FROM ADULTS).

1. Tuberculous.
    Case 17.—Pos. at 1:5. Confirmed by necropsy.
    Case 41.—Pos. at 1:15 on day before death. Diagnosis confirmed by autopsy.
2. Non-tuberculous.
    Case 45.—Typhoid. Pos. at 1:5. *No active or latent* tuberculosis found at necropsy.

HYDROCELE FLUIDS.

1. Non-tuberculous.
    Case 25.—Neg. at 1:5. No reaction in guinea-pig after injection of 15 cmm.
    Case 36.—Neg. Careful search made for tubercles in excised sac.

Summing up these experiments we ascertain the following:

BLOOD SERA.

	Pos.	Neg.	Pos.	Neg.
Non-tuberculous	2	12	15%	85%
Tuberculous	2	..	100	..

PATHOLOGIC EFFUSIONS.

	Pos.	Neg.	Pos.	Neg.
Non-tuberculous	6	14	30%	70%
Tuberculous	12	4	73%	27%

It must be born in mind that except in cases on which autopsies are performed it is impossible to say that latent tuberculosis is not present. The number of tests here employed is much too small to be in itself of any value, but the results agree quite closely with those of the majority of workers.

Very different are the statistics of some others, notably Beck and Rabinowitch,[37] C. Fränkel,[38] Koch,[2] de Grazia[39] and others.[34] The work of Beck and Rabinowitch[40] is of especial value on account of comparative tests with tuberculin and the extensive postmortem examination of tested cattle. Although it has been claimed by Arloing and *Courmont* that there must have been faults in the technic, it is not easy to understand how such gross errors were made. The cultures which they used for their experiments are stated to be identical with those sent to them by Arloing and Courmont for comparative tests. They were unable to discover motility in either their own cultures or in those of the French observers. The following are, in brief, their results:

1. In 19 healthy cattle, 12 were pos. at 1:5.
2. In 4 sick non-tuberculous, 3 were pos.
3. In 17 cattle with incipient tbs., 6 were neg. at 1:5.
4. In 22 moderately advanced tbs., 2 were neg.; 6 were pos. only at 1:5.
5. In 16 advanced cases, 1 was neg.; 4 reacted only at 1:5.
6. In cows inoculated with tuberculosis: 3 were neg.; 5 were pos. at 1:5 only.

In considering these figures it must be remembered that the normal bovine serum has been found to react at *1:5 and that for this reason* a reaction at 1:5 should not be considered positive.

In 73 humans the same variations appeared:

1. Tuberculous (phthisis).
    Incipient (17), 6 pos.
    Advanced (16), 4 pos.
    Doubtful (clinically), but reacting to tuberculin, of 5, 1 pos. at 1:5.
    Lupus (2), 1 pos.
    Nephritis and healed tbs. (1), 1 pos.
    Meningitis (1), 0 pos.
2. Non-tuberculous (31).
    10 pos.; of these some were tested with tuberculin with neg. results.

The same observers find that the sera of some animals, e. g., dog, ass and goat, *agglutinate the test fluid with* great regularity.* Koch, in whose laboratory the above results were obtained, and Fränkel *confirm this work.*

CAUSES OF REACTION.

It is repeatedly asserted by Arloing and Courmont that the cause of the agglutination of tubercle bacilli lies in the formation of an antitoxin which circulates in the blood and appears in the body fluids elsewhere. *Comparison is made frequently* to the antitoxin produced in the course of typhoid fever. In mild cases of tuberculosis, *which go on to a rapid recovery*, this antitoxin is said to be produced in large amounts, while in those which are rapidly fatal it is assumed that the time is insufficient for its production. No rational explanation is offered for its disappearance before death in cases, which extend over a long period and finally produce death chiefly *from cachexia. It* has always been the contention of Koch and his school that the limitation of tuberculous processes is solely a result of the local reactions of the tissue and entirely independent of any systemic changes. There *is no evidence in the large* majority of cases that the bacilli ever enter the blood stream. The very exhaustive work of Trudeau and Baldwin[41] in attempting to obtain an antitoxin from animals injected with both virulent and *non-virulent cultures* of tubercle bacilli gave entirely negative results. Numerous other investigators have arrived at the same conclusion, viz., that in tuberculosis no antitoxin is formed. Recent investigations show, however, that agglutinins and antitoxins may be formed independently of one another.

---

* Ficker[40] explains the wide discrepancies between the results of Arloing and Courmont and those of Beck and Rabinowitch by the age of the cultures used. A. and C. usually employed growths from 9 to 12 days old, B. and R. cultures 14 days old. Ficker points out that inasmuch as the agglutinating material is used up in the reaction, testing fluids very rich in bacilli are not necessarily completely cleared. Therefore sera of slight agglutinating power *may* not produce reactions in cases in which very turbid homogeneous cultures are employed. He also finds that the number of bacilli in a culture after 14 days is much greater than after a *development* of only 10 days.

There is good foundation for believing that the blood serum is so altered at times that precipitation of the tubercle bacillus occurs when it is added to liquid cultures of this organism. Whether or not this property is a specific result of the action of the tubercle bacillus is doubtful. According to Arloing agglutination may be produced by the blood of animals which have been injected with certain chemicals. It also may occur to a considerable extent with serums of many normal animals. On the other hand, similarly prepared cultures of practically all of the known acid-proof bacilli react in the same way to agglutinating sera. But it is extremely doubtful whether these organisms have anything in common beyond their reaction to acids and possibly the presence in them of certain fats.[42] The foregoing considerations warrant the conclusion that the agglutination of tubercle bacilli and the presence of tuberculosis are not necessarily related. Changes which are too slight to be detected by our present methods of chemical analysis may occur in the blood after removal from the body, which render it more easily capable of causing the precipitation of bacilli.* A fluid mixture which spoils even in the dark and in the cold in two weeks after preparation, must be so delicate that even very slight changes in the blood sera might affect it. Many organisms are clumped by ordinary blood in the lowest dilution (1:5) used in this test. In brief, we obtain the reaction in cases when tuberculosis plays no rôle; whether or not tuberculosis produces the agglutinating sera in many cases, remains an open question.

A casual glance is sufficient to show the many stumbling blocks in the way of arriving at a decision of the significance of the reactions. The presence of agglutinating serum in 30 per cent. (Arloing and Courmont) to 62.7 per cent. (Romberg) of those who never have any clinical evidence of tuberculosis must always be confusing to one who attempts by this method to determine the nature of the disease in question. A negative result may mean: entire absence of tuberculous lesions, healed tuberculosis, acute tuberculosis or tuberculous cachexia; and (in the judgment of those who have had the most favorable results) even some of the relatively mild cases do not respond. A positive agglutinative reaction may represent a normal adult individual (according to Nägeli a normal adult individual has some tuberculosis); it may stand for a highly resistant organism struggling against the disease, or it may represent the 70 per cent. of advanced or acute cases of tuberculosis in which the reaction occurs. It is especially in the acute virulent forms that we stand in need of a rapid and efficient means of diagnosis, and it is in these forms that the sero-reaction is, even in the eyes of its most ardent advocates, least trustworthy.

Practically only the newborn never have elements in their sera under normal conditions which cause the precipitation of tubercle bacilli. Romberg concludes from this that this measure should be especially valuable in the young. But, in the young, tuberculosis usually assumes an acute form; hence also under these conditions the serum reaction may leave us in the lurch.

CONCLUSIONS.

1. Under various conditions animal sera agglutinate homogeneous cultures of human tubercle bacilli in liquid media.

2. Such sera may be obtained from the human or animal body without the presence in it of the bacillus tuberculosis.

3. It is doubtful whether the agglutinative powers are ever due to the specific action of the bacillus tuberculosis.

4. The presence or absence in the adult human blood serum of agglutinative properties for tubercle bacilli is no decisive evidence of the presence or absence of tuberculous lesions in the body.

It gives me great pleasure to thank Professor Hektoen for his assistance and encouragement in this work.

THE TRANSMISSION OF YELLOW FEVER.*

JAMES CARROLL, M.D.
ASSISTANT SURGEON U. S. ARMY.

Several American observers have noted that during the yellow fever outbreaks mosquitoes were very numerous, among them Rush,[1] at Philadelphia in 1797; Dr. Weightman,[2] of the U. S. Army, at St. Augustine, Fla., in 1839; Dr. Wood,[3] at Centerville, Miss., in 1853. Dr. E. H. Barton[3] states "that at Clinton, La., in 1853, mosquitoes were uncommonly numerous night and day." At Trinity, La., in the same year, when sawdust was used to fill up low places in the streets, the disease was not propagated, though many cases were brought there and no precautions were used.[3] It is hardly necessary to note what the effect of this obliteration of puddles would be on the development of mosquitoes. Dr. Beyrenheidt[3] of Biloxi, Miss., in reporting a severe epidemic at that place in 1853, during which 533 cases and 111 deaths occurred in a population of 5,520, makes the interesting statement that "mosquitoes and fleas were very abundant." Dr. Bennett Dowler strongly urged drainage of the city of New Orleans, and spoke of the city and its environs as "mosquito lands."[4] La Roche[5] states that in 1793, during the epidemic in Philadelphia, "the narrow streets and alleys near the wharves, as, indeed, in many other parts, were in a foul state, and the gutters almost everywhere sadly neglected." In 1794 Rush and others ascribed the fever to exhalations from wharves, neglected gutters and stagnant ponds.[5] In 1797, during another outbreak in Philadelphia, the condition was practically the same; the Academy of Medicine called the attention of the governor to the putrid exhalations from the gutters, streets, ponds and marshy grounds of the neighborhood of the city.[5] While high temperature, low altitude and the presence of standing water are the conditions most favorable to the development of a yellow fever epidemic, there are numerous instances on record where the disease after introduction spread from house to house throughout the town in places where the general conditions of sanitation and drainage were good. This is now explained by the habits of the mosquito (*Stegomyia fasciata*), which breeds in standing water, in houses as well as out of doors. As a general rule, in ports where yellow fever epidemics first appear, the conditions are known to be favorable for the development of enormous numbers of mosquitoes.

A very interesting observation was made in 1839 in South Africa by Wm. Ferguson, then a surgeon in the South African corps, in regard to the extension of yellow fever from Sierra Leone (where it had been brought on vessels from the West Indies) to Gambia, Goree and Ascension, the subsequent ports of arrival of some of these infected vessels. After mentioning an unusually heavy accumulation of mud and filth in a pit at Ascension, which was said to have been the cause of the fever occurring after an unusually heavy fall of rain, he makes the following statement:[6] "It will be observed that at Ascension, at Goree and at Gambia, a period of three or four weeks always elapsed betwixt the landing of the sick and the epidemic outbreaking of the disease among the population, a degree of uniformity worthy of remark, whether the conclusions at which I have arrived (that the disease was carried to these places on infected vessels) be mistaken or not." These outbreaks were accompanied by black vomit and were undoubtedly yellow fever of imported origin.

Just sixty years later Carter[7] made a similar observation in the United States, shortening the period slightly and giving cases and data. In a later paper[8] he designates the interval between primary and secondary cases the period of "extrinsic incubation."

The known facts regarding the apparent non-contagiousness of the disease, the peculiar manner in which it has been seen to pass from one house to another without intercommunication of the inhabitants, and the numerous points of resemblance between yellow fever and malaria, led us to expect results from mosquito inoculations in yellow fever. After satisfying ourselves that *B. icteroides* (Sanarelli) was not to be considered, Drs. Reed, Lazear and myself, in consultation, decided that the mosquito theory had many facts to support it and could be promptly decided one way or the other. This leads us to a consideration of the mosquito theory of Finlay.

At the session of the Royal Academy of Sciences, Havana, Aug. 14, 1881, Finlay first gave to the world his memorable theory of the transmission of yellow fever by the mosquito, and reported five experiments, which are included in the accompanying table, comprising all of Finlay's and Delgado's positive cases published in 1891.[9]

Finlay believed[10] that the transfer of the specific agent of the disease from patient to non-immune was effected mechanically by the insect's proboscis,[14] and that the infection would be conveyed immediately if the insect chanced to bite a susceptible person a few moments after feeding on a patient in the proper stage of the disease.[11] He also thought that the graver forms of yellow fever might be produced by the bite of *Culex pungens*, because the insect ingested a larger amount of blood than stegomyia, and consequently a greater quantity of the virus would be retained on its proboscis (stylet).[11] He ventured the opinion that yellow fever was a sort of eruptive fever, and that the seat of the eruption was the endothelial lining of the blood vessels, and that the mosquito picked up the inoculable material from the interior of the blood vessels on its biting apparatus and transferred the same to the interior of the vessels of the person subsequently bitten.

In a later paper he assumes that the picking up of these germs by the proboscis of the mosquito is selective, because there is nothing to prove that other inoculable diseases have ever been so transmitted. From four culture experiments, in each of which the head and proboscis of a mosquito was dropped into a bouillon tube, he infers that the head and proboscis of the day mosquito possesses bactericidal properties for ordinary bacteria and fungi with the exception of a coccus, which was subsequently[12] claimed to be the specific agent of the disease.[13] The sting of the mosquito is suggested as the "intermediate host" necessary for some phase of development of disease germs.[14]

As late as 1899 Finlay mentions the isolation of the tetracoccus from culture media into which the heads and proboscides of contaminated mosquitoes had been dropped, as one of the three results of his experiments on yellow fever mosquitoes.

In a paper[13] published in 1895 he announced some very interesting results obtained with the "tetracoccus." A number of rabbits were inoculated intraperitoneally with cultures in bouillon; one of these cultures had been obtained from the head and proboscis of a mosquito by placing them in a tube of bouillon five days after the insect had been a yellow fever patient; the others came from the finger blood and milk of yellow fever patients.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. W. S. Thayer, J. M. Anders and Frank A. Jones.

All of the rabbits died; some of them showed infarcts of the kidneys, lungs and liver. A rabbit obtained from the country was placed in the stable where some of the other rabbits had been kept, and at the end of eight days it was found dead. The tetracoccus was obtained from its heart's blood.

Eleven days after the rabbits had been removed from the house (the stable is usually a part of the house in Havana) a Spanish wet nurse came to spend some time there, and on the third day following her arrival she was attacked with yellow fever. Mosquitoes had been unusually abundant in the house during the whole time the inoculated rabbits had been kept in it, and we are asked to keep this in mind, in view of the possible transmission of the disease from animals to man. We are told that the blood from the finger of this woman on the third day of her illness gave the "pale yellow tetracoccus," and the milk from her breast gave a "white tetracoccus," which proved fatal to a rabbit in fifteen days.[13]

While reading the accounts of these experiments one is constantly reminded of the pathogenic staphylococci. It is strongly suggested[13] that the rabbits died of yellow fever, and it is asserted that the experiments justified the assumption that the tetracoccus was the "specific germ of yellow fever."

TABLE 1.—MOSQUITO INOCULATIONS REPORTED BY FINLAY AND DELGADO IN THE ARCHIVES DE MEDICINE NAVALE, TOME 55, PARIS, 1891.

No. of Case.	No. of Patient.	Date of Contamination of Mosquito.	Date when the Patient was Bitten.	Period in Mosquito.	Date of Attack of Fever.	Period of Incubation.	Character of Attack.	Albuminuria?	REMARKS.
1	F. B. M. .	June 28, 1881 .	June 30, 1881 .	2 days	July 14, 1881. .	14 days	Mild .	Yes	Excessive period of incubation.

The statement is also made in this paper that of one hundred presumably susceptible persons who had received the mosquito inoculation during the fourteen years previous, only three had subsequently died of yellow fever.[13]

I have been unable to find records of these one hundred cases in the library of the Surgeon-General's office, and submit those of which the data are accessible to me. As these include the cases on which Dr. Finlay's claim is based they will suffice for the purpose. The fifty-four negative cases are omitted.

Case 3 was bitten by a mosquito that had been fed on bloody excrement from another mosquito that had been found inside the mosquito net of a fatal case. The material was allowed to dry for twenty-seven days in the test tube and was then moistened with a little sugar and water to prepare it for feeding.[15] There is a marked difference between the method of procedure herein described and that given in 1901,[10] when Dr. Finlay said, "I applied a nocturnal mosquito and allowed it to fill itself from a case of yellow fever. After pricking the side of the insect's abdomen I mixed the blood which escaped with a drop of sterilized syrup and fed with it a fresh culex mosquito, and finally applied the latter to a third soldier (July 29). Two days later July 31, the soldier went to the hospital with a fever which was also recorded as "abortive yellow fever." This case (L. G. P.) was omitted from the paper published in 1881, as stated, but was included in 1891 in the report from which the cases here recorded are taken.

Case 4 is further discussed in English in a foot note on p. 368 of the Revista de la Asociacion Medico-Farmaceutica, Havana, February, 1902. (History of illness vague. Did not go to bed or report himself sick.) The first five cases were newly-arrived soldiers, stationed at Cabanas and who were brought to the city of Havana for examination once in every five days.

Case 9 is cited by Finlay[17] in refutation of our conclusion[18] that the mosquito is not capable of infecting until about twelve days or more have elapsed after it has bitten the patient.

Case 55 was a Spaniard, newly arrived, who lived at a country residence. At both attempts to inoculate him the mosquitoes failed to bite; nevertheless he was taken sick August 26. Another non-immune who occupied an adjoining room was taken sick with similar symptoms, a few days later. No further comment is necessary, except that the cases of the Army Commission and of Dr. Guiteras were kept under close observation and strict control. Nearly all of Dr. Finlay's cases were exposed to infection in the city of Havana. Only four of them come within the recognized periods of incubation, viz., Nos. 2, 3, 4 and 66. The first three of these were inoculated in Havana in July, 1881, during which month there were ninety deaths from yellow fever in that city alone. The last was inoculated in August, 1890. In that month sixty deaths from yellow fever are recorded for the city of Havana.

Finlay has published a great many conjectures and speculations in regard to yellow fever transmission. Some of these, such as the belief that the disease was transmitted by the mosquito, have been proven by our work, but not in accordance with his ideas. I can find no evidence that he has produced a single case of yellow fever by his inoculations. In the first place the mosquito is incapable of transmitting the disease in so short a period as two to five days after biting the patient. In the second place seven days must be placed as the extreme limit of incubation in the human being. Our longest period was between five and six days. Finlay conveniently puts the ordinary limit of yellow fever incubation between five and twenty-two days.[14] The efficiency of the five-day quarantine regulation proves that incubation in man certainly does not extend over six days, or seven at the extreme, and in the thirty experimental cases recorded by ourselves and Guiteras the former period has never been exceeded.

In a letter of Aug. 20, 1901, Dr. Finlay[10] states he was convinced that extension of the interval between the application of the mosquito to the patient, and subsequently to the non-immune, would develop a severe attack, such as he was anxious to avoid. One can sympathize with the humane feeling that prompted him to forego positive proof of his theory rather than run the risk of producing a severe attack, but it is a fact that on Aug. 22, 1901, two days later than the date of that etter, I saw Dr. Finlay apply to a non-immune two osquitoes that had been kept thirty-four days after conamination.[20]

TABLE 2.—NEGATIVE MOSQUITO INOCULATIONS OF THE ARMY COMMISSION.

Number.	Character of Attack and Number of Patients Bitten.	Day of Disease.	Interval in Mosquito. (Room temp.)	Date of Application of Mosquito.	Number of Mosquitoes Applied.	Remarks.

NOTE.—The subjects of Experiments Nos. 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, and 21 were proved to be susceptible by subsequent experimental infection. No. 22 declined a second test. In Experiments 20 and 21 the same set of insects and the same subject were used. Four of these insects infected this man six days later, on Dec. 30, 1900.

I have been impelled to look up the literature of this subject because I have seen several times of late the statement of Dr. Finlay that the Army Yellow Fever Commission has tacitly ignored his right of priority.[21] It is too late, after facts have been proved and recorded by others, to claim priority unless one can point to unmistakable evidence, in print, as proof that the facts have been demonstrated and duly reported. In our preliminary report[22] Dr. Finlay has been given due credit for priority in advancing and advocating the mosquito theory. Nothing more is due to him. He states[21] that he had "many years ago discovered that yellow fever was transmitted by mosquitoes," when in reality he simply assumes that to be the case, and the facts recorded by him do not sustain his claim.[23] He further states[21] that his own work had been singularly misrepresented before the American public, and that "among the facts and conjectures which are attributed to the recent investigators there is scarcely one which had not been asserted, demonstrated or suggested by me, as the result of my personal experiments and observations." One can only express admiration for this eminent scientist's persistent adherence to his theory, but the unbiased observer, after a perusal of his numerous writings, must agree with us that while he asserted and suggested everything that intelligent reasoning and profound knowledge could suggest, he failed to produce a single case of the disease. Our results have been confirmed by Guiteras with eight cases and three deaths;[24] Dr. Finlay's assumed results have never been confirmed by a single investigator. In our "Additional Note,"[25] we report among other instances one in which the bites of fourteen insects, applied four days after contamination, failed to infect, and the seven remaining alive failed also to infect eleven days after contamination, but on the seventeenth day following contamination the bites of four of the same insects produced an attack of yellow fever in "the same individual." During the whole of this time these insects had been kept in a heated room at an average temperature of 82 F. If, as is claimed by Finlay,[26] protection is conferred by one or two bites of "recently contaminated" (two to five days[19]) mosquitoes, this individual, who had received twenty-one bites from recently contaminated insects, should have been able to resist the bites of four of the same insects six and thirteen days later. Should one accept Finlay's extension of the incubation period to twenty-two days infection might then be erroneously attributed to the bites inflicted thirteen days before the onset of fever.

TABLE 3.—POSITIVE MOSQUITO INOCULATIONS OF THE ARMY COMMISSION.

No.	Character and Number of Patients Bitten.	Days of Disease.	Period in Mosquito.	Number of Mosquitoes Used.	Date of Application of Mosquitoes.	Incubation.	Character of Attack.
1	Severe, 1.	2d.	12 days	Room temp. 1.	Aug. 27, 1900. . . .	3 days, 7 hours . .	Severe.
	Mild, 1	1st.	6 days				
	Severe, 1.	2d.	4 days				
	Mild, 1	2d	2 days				
2	Fatal, 2. . .	2d.	2 to 16 days . . .	Room temp. 4.	Aug. 31, 1900. . . .	6 days.	Moderate.
	Mild, 8	1st and 2d. . . .					
	Severe, 7	1st, 2d and 3d. .					
3	Fatal, 2.	2d.	2–15 days.	Room temp. 5	Dec. 5, 1900. . . .	3 days, 10 hours. .	Pronounced.
	Severe, 1	2d.	1–19 days.				
	Mild, 1.	3d.	2–21 days.				
4	Fatal, 1.	3d.	17 days	Room temp. 4.	Dec. 8, 1900. . . .	5 days, 17 hours. .	Mild.
	Severe, 2	2d and 3d.	18 and 22 days. . .				
	Moderate, 1. . . .	3d.	24 days				
5	Fatal, 1.	2d.	19 days	1 (Room temp.)	Dec. 9, 1900. . . .	3 days, 12 hours. .	Mild.
6	Fatal, 1	3d.	20 days	Room temp 4.	Dec. 11, 1900. . . .	3 days, 20 hours. .	Moderate; relapse on 3d day.
	Severe, 2.	2d and 3d	21 and 25 days. .				
	Moderate, 1. . . .	3d.	27 days				
7	Severe, 1	2d.	1–24 days.	82 deg. F. 15	Dec. 21, 1900. . . .	3 days, 23 hours. .	Pronounced.
	Well marked, 2. .	1st.	10-5 and 12 days. .				
	Mild, 1	1st.	4-8 days				
8	Mild, 1	1st.	17 days	4 (82 deg. F.) . .	Dec. 30, 1900. . . .	3 days, 23 hours. .	Mild.
9	Well marked, 1. .	3d.	39 days	3 (82 deg. F.) . .	Jan. 19, 1901. . . .	4 days.	Moderate.
10	Well marked, 1. .	3d.	51 days	2 (82 deg. F.) . .	Jan. 31, 1901. . . .	3 days, 3 hours . .	Mild.
11	Well marked, 1. .	3d.	57 days	2 (82 deg. F.) . .	Feb. 6, 1901	3 days, 6 hours . .	Mild.
12	Fatal, 1.	2d.	16 days	3 (82 deg. F.) . .	Feb. 7, 1901	2 days, 22 hours. .	Moderate.
13	Fatal, 1.	3d.	1–53 days.	4 (Room temp)	Sept. 16. 1901 . . .	3 days.	Severe.
	Fatal, 1.	2d.	3–34 days.				
14	Severe, 1.	2d.	18 days	8 (Room temp.).	Oct. 9, 1901	3 days, 8 hours . .	Mild.

The Army Board worked on an entirely different hypothesis from Finlay, who believed that the infecting agent was retained on the biting parts of the mosquito, that infection was direct and no interval was necessary. The board worked on the hypothesis that the specific agent of yellow fever was probably one of that group of strict parasites that in nature necessarily pass through two distinct and alternating cycles of development, one within the body of a vertebrate, the other within a blood-sucking invertebrate host. Finlay believed that the bite of a single insect would confer a mild infection and multiple bites a severe one. In my own case, produced by the bite of a single insect, a fatal result was looked for during several days. Dr. Lazear was bitten by a single insect and died.[27] I became so firmly convinced that the severity of an attack depended on the susceptibility of an individual rather than on the number of bites sustained, that on Oct. 9, 1901, at Havana, I purposely applied to a non-immune eight mosquitoes (all I had) that had been contaminated eighteen days before. The attack that followed was a mild one, the temperature never reached 103 F., and dropped to normal on the evening of the fourth day.[27]

The original theory of Finlay has been variously modified by him from time to time to meet possible contingencies. *He now evidently inclines to the belief that* development of the germ takes place in the salivary glands of the infected mosquito.[21]

Table 4.—Positive Mosquito Inoculations of Dr. Guiteras.

Number.	Character of Attack and Number of Patients Bitten.	Day of Disease.	Period in Mosquito.	No. of Mosquitoes Used	Date of Application of Mosquitoes.	Incubation.	Character of Attack.
1	Severe, 1	1st	26 days	1	Feb. 23, 1901	3 days, 10 hours	Pronounced
2	Severe, 1	3d	19 "	4	Aug. 8, 1901	4 " 5 "	Fatal
3	Severe, 1	3d	19 "	1	Aug. 8, 1901	3 " 3 "	Mild
*4	Severe, 1	3d	20 "	3	Aug. 9, 1901	5 " 3 "	Fatal
5	Severe, 1	3d	24 "	1	Aug. 13, 1901	3 " 19 "	Mild
6	Severe, 1	3d	24 "	2	Aug. 14, 1901	3 " 21 "	Fatal
7	Severe, 1	3d	21 "	3	Aug. 11 1901	5 " 21 "	Moder'ly severe
8	Severe, 1	3d	34 "	2	Aug. 22, 1901	3 " 0 "	Severe

*Case 4 had been bitten with negative result ten days previously by four mosquitoes five days after they had bitten a fatal case in the third day. of the disease. See Case 33 of Guiteras' table, Amer. Med., Nov. 23, 1901, p. 811.

A complete proof or disproof of his claim of positive results for his recorded inoculations could easily be obtained by means of a series of innocent experiments. It is interesting to note that at the very time when this distinguished authority is in position to confirm the results of his first inoculations, if they are susceptible of confirmation, he takes the ground that inoculation experiments on human beings in Cuba must be strictly forbidden.[21]

It is unfortunate that Dr. Finlay in his numerous contributions to this subject very seldom gives exact references that would enable one to compare his more recent assertions with his former statements. In regard to his expressed opinion that the great merit of our work consists in our having accurately defined the danger line, beyond which there is a risk of producing severe or fatal experimental cases when non-immunes are inoculated with mosquitoes whose contamination is more than ten days old,[21] I desire to record my belief, based on experimental observation and on the results obtained by Guiteras, that it is impossible to confer protection or to produce infection of any grade, with an insect that has been contaminated less than a week, and that inoculations with a mosquito contaminated for a shorter period will be absolutely devoid of result. The accompanying tables, compiled from our and Guiteras' cases, afford a substantial basis for the assertion. I deem it a duty to the service to which I belong, to my dead colleagues (Reed and Lazear) and to the profession, to state the facts plainly and clearly. I do not expect that this paper will remained unanswered; nevertheless, I shall decline to engage in controversy and leave the final determination to those who are competent to judge, after they have carefully perused the publications herein referred to.

The mosquito theory has been practically demonstrated by the army commission and Dr. Guiteras in two series comprising twenty-two cases in all. The non-communicability of the disease by means of fomites has been a matter of common observation in certain localities, and has also been demonstrated practically by our own experiments and those of Havard and his associates. Yellow fever, therefore, is not a filth disease, in the strict sense of the term, and filthy accumulations are dangerous in this connection only, when accompanied by sufficient moisture to breed mosquitoes under favorable conditions of temperature. Under such conditions standing water is a source of danger, within dwellings or without, and whether dirty or clean, unless it be kept covered or is changed every few days. Yellow fever is a preventable disease; quarantine, if effective, will exclude it, but if the quarantine be evaded and cases gain entrance to a city the disease can be absolutely controlled and finally exterminated by measures directed against the mosquito alone.

Carter[7] has well shown[8] that first cases are not dangerous until after the lapse of a number of days, for, in his experience, persons in direct contact with them for a few days only never developed the disease after being placed in quarantine. This applies only to the first cases occurring in a town or neighborhood. He found that secondary cases did not appear until the expiration of a number of days varying from 11½ to 29, the average being eighteen. This interval represents the time necessary for the mosquito, after biting a patient, to become capable of infecting, plus the period of incubation in the person bitten.

The greatest obstacle to the control of this disease is the failure to recognize the first cases when they are not accompanied by black vomit. Some of these cases are so mild in character that no physician would dare to pronounce them yellow fever unless he knew the disease to be prevailing at the time. Susceptible persons visiting the house or living in adjoining houses would be bitten and develop the disease in near or distant localities several weeks later, forming secondary foci of infection. From these secondary foci tertiary foci would in time develop. The diagnosis of bilious remittent fever, dengue, etc., would serve to cover the earlier cases until the appearance of black vomit, by which time the infection would have become more or less widely disseminated. Such is the history of many outbreaks.

The number of mosquitoes in infested districts can always be appreciably diminished by giving attention to surface drainage and the removal of standing water, no matter how small the quantity or how pure the quality may be. Rain-gutters and conduits on buildings should be kept clear and free; cisterns, wells, flush-tanks and other permanent receptacles for water should be kept tightly covered or securely screened; privies and cesspools should be cared for; air vents to cisterns and wells protected by screens; and water should never be permitted to stand in any vessel or receptacle within a building longer than three or four days. Ditches and open drains containing water should be frequently flushed; old cans, crockery, etc., should be removed from the vicinity of dwellings; pools or ponds should be stocked with fish and deepened at the margins or treated with petroleum. As the stegomyia is largely a house-dwelling and a house-breeding insect, these and other similar measures will surely diminish their number and add to the general comfort and protection. In places exposed to yellow fever infection all fever patients should be protected, night and day, from the bites of mosquitoes by the use of netting and wire screens. Strict quarantine measures, local and general, with the isolation of patients and extensive and thorough fumigation of the localities where they are found will insure suppression of the disease wherever it may appear.

In the suppression or control of yellow fever disinfection, apart from fumigation, is a waste of time and money. Natural yellow fever is transmitted by the mosquito, and always and only by the mosquito. The harmlessness of fomites has been fully demonstrated by our experiments in 1900 and 1901, in which three young Americans slept for twenty consecutive nights in a room garnished with articles soiled with black vomit, bloody fecal discharges and urine from fatal and other cases of yellow fever. Three and four large boxes were packed and unpacked with these articles night and morning by these non-immunes, who suffered no disturbance of health from these exposures. The room was twenty feet by fourteen feet, double walled, tightly ceiled, heated to above 90 F. and dark. Water was always present to keep the atmosphere moist. Two other non-immunes then occupied the room for twenty nights while additional articles of bedding and clothing were added. They slept in the garments and between the sheets that had covered cases of yellow fever, some of which were fatal. The result of this second exposure was *nil*. A third attempt was then made with two additional non-immunes equally without success. Not the slightest indisposition followed close and intimate contact with this repulsive material in any case. Temperatures and pulse rates were recorded at regular and frequent intervals. Four of these seven non-immunes were subsequently infected by blood injections and by means of infected mosquitoes. A fifth resisted the mosquito once[28] and declined further attempts at inoculation.

Yellow fever has been eradicated from Havana, one of its endemic homes, by the institution of measures directed against the mosquito, after extreme cleanliness and energetic disinfection had proved a dismal failure. Several cases subsequently imported into that city have been handled with impunity by guarding the patients against the bites of those insects. A small outbreak in Santiago de las Vegas in 1901 was promptly suppressed by Colonel Gorgas by the use of means directed only against the mosquito. On those who decline to accept such evidence must rest the burden of proving that the disease is transmitted in some other way before their position can be sustained.

THE STEGOMYIA AND FOMITES.*

STANFORD E. CHAILLE, M.D.

NEW ORLEANS.

As a student since 1851 of yellow fever, especially of its causation and prevention; and as a citizen of New Orleans, who has shared its blighted prosperity and its grief, greater, because of this disease, than has afflicted any other place in our country, I deem it my first duty to express most profound and grateful appreciation of those who have, since 1900, contributed facts of incalculable value for prevention and for commerce.

The notable experiments of Dr. Walter Reed and his assistants, Drs. James Carroll and A. Agramonte—added to and strengthened by the researches and labors of Drs. Carlos J. Finlay and John Guiteras, of Drs. W. C. Gorgas, John W. Ross, H. R. Carter and probably others—and rendered possible by the official encouragement and aid of Surgeon-General Sternberg, U. S. A., and of Governor-General Wood, M.D., have contributed to our knowledge of yellow fever facts that I hope and believe will prove of greater value than all the facts gained by all preceding students of the disease. The names cited deserve the earliest place on the roll of honor of the twentieth century, the century probably destined to become unprecedentedly illustrious for additions to the best of all knowledge, that which contributes to the health and welfare of mankind.

These investigators have contributed four sets of precious facts:

First—Fresh blood or its serum, taken from a case of yellow fever during the first days of the attack, will give the disease, if hypodermically injected into a non-immune. Hence the blood contains the poison, probably an ultra-microscopic germ, as I maintained in 1880, and this poison, when fresh, is infective without undergoing any change outside of the body.

Second—The female stegomyia, serving as an intermediate host, can convey the poison to non-immunes. In 20 experimental cases (Reed's 12 and Guiteras' 8) the stegomyia became infected by sucking the blood during the first four days of the attack, but not later; and an interval of at least twelve days was required to infect a non-immune. However, it deserves note that no one has stated or proved that more numerous experiments might not have yielded some cases wherein the four days' time would have been prolonged and the twelve days' interval shortened. The facts thus far stated have not, I think, been denied by any one.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. W. S. Thayer, J. M. Anders and Frank A. Jones.

Third—Excluding all mosquitoes, fomites prepared and kept under all the known conditions, universally supposed to be the very best, for supplying the most virulent fomites, failed in December and January, though an artificial summer heat was maintained, to infect seven non-immunes extraordinarily exposed to said fomites. In a second trial the following September and October, 1901, under like favorable conditions, eight non-immunes also escaped infection. These negative results in two trials, involving fifteen non-immunes, have been confidently claimed to be conclusive of the impotency of fomites ever to infect; and this claim has been as confidently denied, because, as is said, of many facts explicable by fomites but inexplicable by the stegomyia.

Fourth—Disregarding filth and fomites, because two years of warfare against them had proved ineffectual, and limiting sanitary measures solely to excluding imported cases, to isolating every home case that did occur and to preventing in every possible way the access of mosquitoes—these measures were followed in Havana by the total disappearance of all home cases from Sept. 28, 1901, to May, 1903.[1] Note in this connection that not less than eight cases have been imported during this time, but these cases have been isolated and carefully protected from mosquitoes, and that there have been in Havana an abundance of non-immunes. Now these four facts, introduction of imported cases, presence of many non-immunes, protection from mosquitoes and freedom from yellow fever in Havana, annually infected for at least 140 years, and monthly certainly for forty-five years and probably longer, were either cause and effect or the most extraordinary coincidences in the history of yellow fever. The more numerous such coincidences may become the stronger the proof of cause and effect. Several such coincidences have already been reported, viz., at Las Animas Hospital, Havana, 1899 and 1900, at Las Vegas, 12 miles from Havana, 1901, and at Havana, 1901, 1902 and to May, 1903.

Further, freedom from yellow fever, though stegomyiæ were present, would not be conclusive evidence against them; though present they might not be infected; and, if infected, very many would die prior to the twelve days requisite to become infective, and those that lived long enough to become infective might fail to gain access to non-immunes, and such failures would be the more probable the more numerous the immunes. Still further, the following reports are suggestive. It is now generally conceded that without anopheles there is no malaria. However, localities are reported from Italy, France and other countries where, although malaria once prevailed, it no longer occurs, and yet this failure to occur coexists with the annual importation of malarial cases and the continued presence of many anopheles. And a locality is reported in England where anopheles refused to suck man's blood.

The case of fomites versus the stegomyia is of the utmost importance for prevention and commerce and now deserves consideration. The only advocates of fomites known to me who have published their views are two distinguished sanitary officers, having much knowledge of and experience in yellow fever, Dr. John H. Purnell of Mississippi and Dr. Edmond Souchon, president of the Louisiana State Board of Health. The arguments of one or the other, to prove that the stegomyia is not the sole cause, but that fomites are also a cause, will be summarized also under four heads.

First—It is claimed that the freedom of Havana from yellow fever in 1901 and 1902 was not due to the warfare on mosquitoes, but to the rigid exclusion of imported cases and to the dying out of the disease. In support of this claim there is some evidence that other Cuban cities escaped yellow fever without effective warfare against mosquitoes. But, even if this evidence were indisputable, there are good reasons for believing that imported cases were excluded, that any cases that did occur were isolated and access of mosquitoes to them was prevented, and that these cities had very few non-immune inhabitants. For such reasons these cities may have escaped yellow fever consistently with the stegomyia theory, although these cities may have failed to wage effective warfare against mosquitoes.

The tendency of yellow fever, as of other infectious diseases, to die out, in spite of the coexistence of some cases and of many non-immunes, has been manifested many times even in the distant past, when imported cases were not excluded and when there was no warfare against filth, fomites or mosquitoes. A cause of this tendency of yellow fever may be a scanty reproduction in some years of the stegomyiæ, as occurs with other insects. In spite of this tendency, it is certain that this has failed for 140 years to manifest itself in Havana to an extent at all comparable with the remarkable cessation of the disease since warfare against mosquitoes was begun. Hence, the extraordinary escape of Havana, the worst and the longest infected city in the world, inclines the probabilities strongly in favor of the claim that its rescue from yellow fever is due to warfare against the stegomyia.

Second—The frequent return or recrudescence of yellow fever six, twelve or more months after a cold winter and without the reintroduction of the infection, is incompatible with our present knowledge of the duration of life of the stegomyia. The greatest duration yet reported was found by Dr. John Guiteras in 1902. Of eleven infected stegomyiæ two died by the tenth day, five were dead by the sixty-fifth day, and of the remaining six the last one lived to its one hundred and fifty-fourth day. It deserves special notice that 18 per cent. died before the twelfth day, i. e., too soon to have become infective, and that this mortality occurred in captives well protected from the many enemies mosquitoes are exposed to in the open. Dr. H. A. Veazie has reported that of one hundred New Orleans mosquitoes one-half died in the first week and only two were alive on the thirtieth day. Manifestly a mosquito's life will vary with its protection from enemies, with its food, temperature, light and other variable conditions. How long an infected stegomyia may possibly live under the influence of hibernation and other exceptional conditions is yet to be determined. However, Dr. John Guiteras[2] has reported that of thirty-three female stegomyiæ kept in an icebox at 40 to 50 F., and without food or water, three lived to the eighty-seventh day and were then destroyed by ants.

My consideration of recrudescence will be limited to criticisms on one example cited oftenest, cited recently by Dr. Purnell and by Dr. Souchon, cited also by Dr. Sternberg and by myself in 1880, when, however, every one believed in fomites and no one in stegomyia. Hence, my reinvestigation of the supposed recrudescence in Memphis in 1879, after its epidemic of 1878, the most fatal one, proportionately to population, ever in the United States.

---

[1] The warfare against mosquitoes in Havana was begun Feb. 27, 1901; preventive measures against filth and fomites were abandoned July 1. There were twelve deaths in January and February, but only six deaths March 1 to Sept. 28, 1901, and none since; with the sole exception that of seven *imported* cases of yellow fever in 1902, two died.

[2] Revista de Medicina Tropica of Havana, April, 1903.

The best authority for this recrudescence was Dr. G. B. Thornton, the thoroughly trustworthy president of the Memphis Board of Health. He reported[3] that the first case was attacked about the 5th, was reported on the 8th and died the 9th of July; that, although in all preceding epidemics the first case was known to have been imported from New Orleans, yet in 1879 no such case was discovered; and further, that yellow fever was not then "prevailing" in any part of the United States. From these premises Dr. Thornton and most of the medical profession concluded that the disease was due to "local origin," which, in this case, meant to houses and their contents infected in 1878, i. e., to the recrudescence of the dormant vitality of infected fomites. A conclusion in full accord with the professional opinion of 1879.

To these facts and to this conclusion I now add, for the first time, I believe, in this connection, the three following facts: Dr. W. L. Coleman,[4] an inspector of the National Board of Health, maintained that the disease was certainly due to a fresh importation of fomites, viz., to two box-cars of bananas from the West Indies, via Havana and New Orleans, that arrived in Memphis prior to July 4, 1879. Further, Dr. Thornton's final conclusion was that "the disease may have been imported. If such was the case, the epidemic was, in my opinion, due to two causes, importation and local origin." Still further and more important, while it was correctly stated that yellow fever was not "prevailing" anywhere in the United States, none the less it did exist in New Orleans, as proved by the annual report of the Louisiana State Board of Health for 1879, wherein is recorded one imported case, March 26, one home case on the 16th and another on the 17th of June. Evidently, then, there was time sufficient for stegomyiæ to be transported, by the open communications then existing, from New Orleans to Memphis to infect the first case reported in Memphis. These facts prove that this alleged recrudescence might have been due to stegomyiæ and not to fomites. Conjoin the indisputable fact that the first cases reported in New Orleans have often not been the first that occurred and the case of the stegomyia becomes still stronger. It is doubtful whether, if all the facts could be known, other instances of recrudescence by *fomites* would *not* become as questionable as the most often cited of all instances, Memphis in 1879.

Third—In behalf of fomites it has been urged that non-immunes in camps of refuge, infested by mosquitoes and near infected cities, have been kept free from infection by the destruction or disinfection of fomites. This conclusion is very far from proven. Such cases of the disease as were imported were usually promptly isolated; quite possibly there may have been swarms of mosquitoes, but no stegomyiæ, for these seem to prefer houses and to "shun rural districts and open fields"; and there may have been stegomyiæ but none infected. Further, New Orleans could furnish many instances of adjacent places in the country, and of hospitals, asylums, jails and convents within the city, into which places cases of yellow fever were introduced but failed to originate any cases though fomites were neglected. Such exemptions occurred frequently in the distant past, when no efforts were made either to isolate the disease or to disinfect fomites. It seems to me that all such exemptions are more explicable by the absence of infected stegomyiæ than by the fomites theory.

Three instances, often cited, of exemption from yellow fever will illustrate the claims of advocates of fomites. In 1878 many hundreds of refugees fled from Memphis to Camp Joe Williams, four and a half miles distant. Fomites were destroyed or disinfected, and although there were imported into this camp 186 cases of yellow fever, of whom 58 died, yet no cases originated in this camp. However, Colonel Cameron,[5] commander of the camp, reported the following facts: "Four grave diggers and one carpenter, on constant duty at the hospital carrying the sick, washing the bodies, sleeping on infected bedding, in tents, wearing clothing stripped from the bodies of deceased, remained on said duties seven weeks with perfect impunity from attack." "None had previously had fever." Now if many refugees owed their escape from yellow fever to destruction of fomites, what protected these five non-immunes from fomites not disinfected?

The epidemic of 1878 in Memphis, *with not one-sixth* the population of New Orleans, caused over 5,000 deaths, while there were less than 5,000 in New Orleans. However, in 1879 Memphis had "1,532 cases and 485 deaths" by yellow fever, while New Orleans had only 48 cases and 19 deaths, and 34 of these cases and 12 deaths were restricted to a limited section of the city. Now this comparative exemption of New Orleans was claimed to be due to the vigorous co-operation of the state and national boards of health and the Sanitary Association in the repeated cleansing and renovation of infected places, in thorough disinfection and in the sulphur fumigation of houses.

Further, in 1882 there were only four reported deaths in New Orleans, and this comparative exemption was claimed to be due to thorough cleansing and disinfection of the section surrounding the focus of infection "for at least four blocks each way around the focus." Now, it is notable that in the last two instances sulphur fumigations were vigorously applied—the very remedy specially recommended to destroy stegomyiæ.

Fourth—Reported cases of two kinds have been urged as explicable by fomites, but inexplicable by stegomyiæ. Some cases of yellow fever have been reported where the possible infection of stegomyiæ and the transfer of the infection to the person attacked gave intervals of only 8, 9 and 10 days instead of the least interval of 12 days found in the twenty experimental cases. More experimental cases *might* have proved the possibility of a less interval than 12 days, but a more serious criticism is that the briefer intervals were based on supposed knowledge of what was the very first case, very often too doubtful to justify a final conclusion.

Numerous other cases are reported to have followed, within the usual period of incubation, exposure to fomites under conditions such that the presence of any *infected mosquitoes* was highly improbable *if not impossible*. In some of these cases the disease was limited to the few non-immunes exposed to the fomites, while other non-immunes in the very same house were not attacked. In such cases it is a notable and suspicious fact that even the fomites from those attacked failed to infect the other non-immunes in the same house.

All of these reported cases, as well as some other issues, are amenable to the two following criticisms: Every reporter seeking a cause is not only apt to find it in whatever may be universally admitted to be a cause, though not one, but is also apt to overlook a universally unsuspected cause, though this be the true one. There have been many reported cases of disease explained satisfactorily to reporters and their readers by witches, the moon, comets, bile, urea and other erroneous causes. Without anopheles malaria does not occur, yet the very word falsely assigns bad air as the cause, and this disease has also been often attributed not only to bad water, but also to watermelons, and these causes have been maintained by evidence satisfactory to reporters and their readers.

[3] In Vols. v and vi, Transactions of the American Public Health Association and in recent letters to me.

[4] See "Yellow Fever and Dengue," by W. L. Coleman, M.D., pp. 100-2.

[5] Transactions of American Public Health Association, p. 155, vol. v.

Many cases of yellow fever in adults, many more in children and negroes, can not be diagnosed by the best experts, and much more numerous must be the cases undiagnosable by the great majority of physicians who are not experts. Over fifty years' study of yellow fever, eight of these years living day and night in the hospitals of New Orleans, when the disease annually prevailed, and six more of these years employed as a United States sanitary officer specially for yellow fever, and given unusual opportunities for investigation, would justify me in swearing in court that the first cases officially reported in a civil population are very often and, as I believe, usually not the first cases that occurred. This is due not merely to diagnostic deficiencies, but also to two other causes, viz., lack of opportunity among the numerous poor unvisited by a physician, and the very frequent neglect of physicians to report their first cases, even when diagnosed. This neglect is due to their unwillingness to become, in public estimation, odious alarmists and also to subject their patients and the families of their patients to disagreeable notoriety and often to legal restraint by sanitary officers. Practical sanitarians are forced to recognize that the more the financial welfare of the public is threatened by the invasion of a communicable disease and the greater the legal restraint imposed on the public and on the sick and their families, the fewer will be the cases reported. For reasons now stated conclusions based on supposed knowledge of first cases are often untrustworthy.

Three more sets of facts pertinent to my subject deserve brief attention. Dr. H. R. Carter,[6] the author of the best summary known to me of arguments in favor of the stegomyia, urges this very weighty generalization. He claims that every disease having an intermediate host is propagated solely by its special host and never by fomites. Though convinced that present knowledge favors this generalization, I doubt whether we yet know enough to justify a final conclusion. In any case, claims for the infectivity of fomites would be more explicable should knowledge enlighten our ignorance in the following particulars.

Of these diseases malaria and the Texas cattle fever spread by a special tick, are best known in our country and most resemble yellow fever. It deserves note that the tick fever, besides other resemblances to yellow fever, has these two striking ones, the young have usually very mild attacks and an attack confers immunity. Now, the infecting germ persists in malaria often for months and years and in cattle fever probably for life; and this long persistence of the germ in healthy immune cattle caused until recently the erroneous belief[7] that infected ticks infected their own eggs. However, my present point is that while the blood in malaria and in cattle fever remains infective long after the first attack has ended, yet the twenty experimental cases indicate that the blood of a yellow fever patient is infective during only the first four days of the attack. The lack of resemblance thus indicated justifies the suspicion that a closer resemblance may yet be proved. A ray of light may yet be found in Finlay's belief that in malaria man is the permanent and anopheles the temporary host, while in yellow fever man is the temporary and the stegomyia the permanent host.

Further, Dr. Patrick Manson, one of the best authorities on malaria, gives good reason for his beliefs, that the malarial germ may have other host than man, and that this germ may be deposited in the soil, inhaled in dust and thus cause the disease. And many good observers still maintain that drinking water may become infectious by the dying therein of infected mosquitoes, as is still taught by some to be the case in filariasis. Still further, Dr. Carlos J. Finlay believes that the fresh blood of yellow fever on the proboscis of a stegomyia can infect a non-immune within the usual period of incubation, while the germs within the stegomyia would require twelve or more days to become infective. I have now indicated five particulars, as to which future knowledge may throw light on the causes that have led to belief in fomites.

The history of the remarkable change of view in New Orleans as to belief in fomites is instructive. A great majority of its physicians, myself included, firmly believed, until at least 1867, that yellow fever originated in this city as was then universally claimed as to other habitually infected cities, and all of this great majority unhesitatingly testified that they had never observed a single case either of direct contagion or of infection by fomites. As steamboats and railroads multiplied and many adjacent places on the routes of travel became infected after outbreaks of the disease in New Orleans, the conviction gradually gained ground that yellow fever did follow the routes of travel and was an infectious disease. Then followed numerous reports that some places on these routes had not had any case of yellow fever introduced therein, certainly the usual precursor of an outbreak, but that fomites had been introduced. Our imaginations failed to invent any explanation for these credited reports except infection by fomites. However, this concession to fomites was made very grudgingly, because New Orleans physicians could not ignore their innumerable experiences of the failure of fomites to infect. Hence the hypothesis invented to explain these credited reports was that, while fomites were usually innocous yet that under the rare influence of some unknown mysterious conditions fomites did become infectious.

For such reasons I, as soon as convinced that mosquitoes did follow the routes of travel and that the stegomyia was a conveyer of yellow fever, embraced the stegomyia as a welcome substitute for those unknown mysterious conditions about which I have wasted, as I now believe, many weary hours of study; and I earnestly hope that the future may permit my brain to rest in peace with the comprehensible stegomyia—unvexed by the incomprehensible, mysterious hoodoo, fomites. I, like others, have advocated fomites, always, however, citing my authority. For my part, I have never secured satisfactory proof of a single case either of direct contagion or of infection by fomites. I have investigated reported cases of infection by fomites, and I have known several cases, supported by very strong evidence, which, after laborious investigation, were conclusively traced to a usual cause, viz., to infected houses wherein were women of easy virtue. These had received night visits, carefully concealed and denied by men who, living in uninfected country places, had contracted the disease in said infected houses, and not by fomites in their uninfected country places.

[6] Bulletin No. 10, Yellow Fever Institute of U. S. Bureau of Public Health and Marine-Hospital Service.

[7] According to Dr. D. E. Salmon, Chief of U. S. Bureau of Animal Industry.

Finally, it deserves consideration in behalf of sanitary officers who hesitate to abandon the disinfection of fomites, that more places than New Orleans have suffered by numerous advocates of innumerable "sure cures" and sure preventives for yellow fever. Notable among these advocates was Gen. Benjamin Butler, U. S. A., in 1862. He, whose memory is still odious in New Orleans, issued in 1863 a pompous farewell address in which he proclaimed: "I have demonstrated that the pestilence can be kept from your borders." His sure preventive was cleanliness, enforced by sanitary regulations, executed by an efficient sanitary police. However, conjoined with this sure preventive the U. S. Navy effectually blockaded New Orleans. General Butler's sure preventive was heartily indorsed by many medical officers of the Army, by northern physicians generally, by public and medical press and by many eminent sanitarians. Among these was Dr. Elisha Harris of New York, who had held several of the highest positions as a sanitary officer and became a president of the American Public Health Association. His advocacy was so conspicuous and enthusiastic that I replied to General Butler's claim[8] and closed with this question, which has never yet been answered: If New Orleans was saved from yellow fever by General Butler in 1862, when there were two reported deaths, who saved New Orleans in 1861, when there was not one reported case or death, and when blockaded New Orleans was occupied by General Lovell and his very many non-immune Confederate soldiers, who enforced no preventives of any kind?

CONCLUSIONS.

My reasons have now been indicated for the five following conclusions: The probabilities now are that the stegomyia, the only cause yet proven, is the sole cause for the dissemination of yellow fever; but that time is required to convert these probabilities into certainty. Boards of health, should they neglect any practicable measure of warfare against the stegomyia, would deserve the severest punishment of the worst criminals. Southern boards of health are excusable for over-precaution against yellow fever. States adjacent to Louisiana have power, by sanitary restrictions, to strangle the commerce of New Orleans and Louisiana should not abandon the disinfection of fomites until approved by said states. Boards of health are representatives of the people and are justified in continuing to disinfect fomites as long as public opinion may favor this measure and until the probability of its inutility is converted into certainty.

To my many friends who urge that Mrs. Stegomyia has inherited all the claims of her father, Mr. Fomites, who is dead and ought to be buried, I tender the advice given at a numerously attended funeral by the undertaker: "Gentlemen, gentlemen, please don't crowd the mourners"—mourners over the remains of Mr. Fomites!

DISCUSSION

ON PAPERS OF DRS. CARROLL AND CHAILLE.

Dr. Edmond Souchon, New Orleans—It is impossible not to be deeply impressed by the reading of the experiments made by Reed and his associates in Havana. The simple, direct, positive, American-like manner in which these experiments were conducted can not but fill our minds with noble pride, as scientists, as men and as Americans. As such I would most probably have joined also the army of followers that have been conquered by the immortal Reed, but as the responsible officer of the Louisiana State Board of Health, the duty of which Board is to guard the valley of the Mississippi against the introduction of contagious diseases, I am compelled to carefully examine into every point, and to submit all the statements, past, present and future, to the crucial test of the Pasteur law, in accordance to which no facts should be accepted as thoroughly proven until all possible means to disprove them have failed. It is because Pasteur applied this law to his own work that not one of Pasteur's statements has ever been refuted.

At the outset, kindly note the words "responsible officer." The sense of responsibility for the awful consequences of possible errors changes the whole aspect of questions. The irresponsible ones are always quick to urge on. When they meet with reverses they naively say that they never would have thought that possible, and that is the end of it.

But when responsible officers have to face the introduction of contagious diseases, the press, the people, the authorities, all unanimously shout that they should have known better, should have been more prudent and more slow in applying new theories; and general condemnation is forever attached to their fair names. But a few years ago all these tragic events were enacted in this very city.

Then, there comes in also the overpowering consciousness of the dire calamities, the sufferings, the anxieties and the sorrows of sickness and the deprivations and ruins or quarantines. All this is properly calculated to cause responsible officers to be doubly careful before making any changes in quarantine regulations which may be followed by pestilence and quarantines.

The factor of responsibility is well illustrated by the following anecdote: A very high health official once had presented to him for signature a telegram relating to a very important quarantine matter. The chief scanned the prepared telegram most carefully, then said to his assistant that since he had charge of that department to sign the telegram himself. The assistant retired and it took him two hours to find the wording of a telegram which he would sign and be responsible for the consequences. On going over the records of all the quarantine stations, state and federal, to which he could have access to and also over the scanty literature on the subject, the writer of the present was confronted with a number of cases of yellow fever where it was impossible for him and his responsible colleagues to see the intermediation of the mosquitoes, bearing in mind the fact that the mosquito does not live more than five days without water in the summer months.

We have collected 27 such cases in the meager literature of the day. Some are land cases and some are shore cases. However much I would like to read some of them to you, the time allotted me will not permit.

If such cases have been observed there have surely been many which have not been recorded. If such cases have presented themselves in the past, similar cases may again present themselves, and how can we safely ignore them in our quarantine regulations until they have been explained satisfactorily to the responsible officers.

To say that these cases are errors of diagnosis is begging the question. Reasonable men will admit that some of the cases may have been diagnosed wrongly, but reasonable men will also admit that it is unreasonable to say that all the cases were mistaken cases.

The first and foremost perplexity of the responsible officers was the question of the treatment of fomites. From the known experiments made by Reed and Carroll, Guiteras and Ross, it is contended that the disinfection of such is unnecessary. To these experiments the responsible officers oppose the fact that they were made at a time of the year when yellow fever is not at its worst, except perhaps the early experiments of Ross.

Then we must consider that 30 per cent. of the non-immunes bitten by infected mosquitoes did not develop yellow fever. It soiled and these men slept with their heads between these bloody towels. They, too, came out in perfect health. Gentlemen, I believe positively that fomites are perfectly harmless. The material was kept there for several months and then removed without any precautions, sent to the laundry, and no one who handled them contracted yellow fever. Of 7 individuals experimented on, four subsequently contracted the disease from the bite of the mosquito and the subcutaneous injection of infected blood. There was no question as to the susceptibility of those infected. All were Americans. These experiments were reported in 1900, in August, by Drs. Guiteras and Ross, and another physician of Havana, and all with the same results.

---

[8] In the New York Sanitarian, August, 1882.

After such experiments I contend that the burden of proof rests with the other side. On those who decline to accept this practical demonstration rests the burden of proof, and they must prove that the disease is transmitted in some other way. If it can be proven that the disease is spread by fomites we are willing to yield. I do not believe there is any doubt that our results will be confirmed, as they have already been so far by certain investigators. It has been found that those who suffer from the disease can be handled with impunity by nurses without any extension of the disease. Personally I believe that if there was no quarantine and no disinfection the disease could be excluded or prevented from spreading by proper precautions. Of course, that would result in placing everyone beneath a mosquito bar and protecting them by wire screens. Then there would be no possibility of spreading the disease. There are no cases of yellow fever now in Havana except imported ones. In regard to Dr. Souchon's statement with reference to the vessels arriving at the port of New Orleans after trips from South America and with the fever developing among the passengers five or six days after arriving at quarantine, they probably were infected after their arrival at the quarantine stations. There is an immense amount of literature on this subject.

COMBINED INTRA-UTERINE AND EXTRA-UTERINE PREGNANCY; OPERATION AND RECOVERY.

G. J. HAGENS, M.D., and J. J. MOORHEAD, M.D
CHICAGO.

A perusal of the literature and the failure to find the coincidence of intra-uterine and extra-uterine pregnancy mentioned in a number of the latest text-books would indicate that this form of gestation is certainly infrequent.

B. B. Browne[1] gives a report of the published cases, 23 in number, dating from 1708 to 1880, and adds a case operated on by H. P. C. Wilson of Baltimore.

Straus[2] states that no fewer than 32 instances of tubal pregnancy coexisting with intra-uterine gestation appear in literature. In Straus' table the maternal mortality amounts to 14 in the 32, but 10 of the 14 were in cases dating from 1820 to as far off as 1879. In 13 cases both extra- and intra-uterine pregnancies continued to term; in 4 both fetuses were living, and out of these 4 only 2 were cases in which both fetuses were delivered alive, the one normally, the other by abdominal section. But one mother was lost out of these 2 cases. In 3 cases one pregnancy alone continued till term, in 2 it was the normal gestation, in one uterine abortion occurred at the sixth week and tubal pregnancy continued to term. In 5 cases the simultaneous pregnancies were diagnosed before uterine labor or operation. In 9 cases the diagnosis was made after spontaneous termination of the uterine pregnancy. In 6 cases it was not made at all, being discovered at necropsy; in 6 cases it was detected during abdominal section, in 2 after abortion of the uterine pregnancy, in 2 at an abdominal section after abortion, in one after detachment of the placenta from the uterine cavity, while in one intra-uterine pregnancy was not detected until two months after the tubal sac had been removed. This is the only case in which, after that operation, uterine pregnancy continued to term. The child was living and was reared.

Our contribution is as follows:

Mrs. J., aged 33; housewife; married 12 years; mother of five living children; youngest child born three years ago.

Since she first menstruated, at 12 years of age, this function has been regular and painless. Had typhoid fever eight years ago. No definite history of pelvic disease.

Last menstrual period began Oct. 20, 1901; usual duration of five days. One month later she noticed a bloody discharge from vagina. Two weeks later she complained of pain in right lower abdomen, also frequent and painful urination. Treated at this time for supposed bladder trouble. On December 18, while seated in a chair, she was suddenly seized with intense cramp-like pain in right groin, accompanied by cold sweat and faintness. Rest in bed for thirty-six hours afforded relief, although she was unable to perform her usual household duties. Bleeding continued at intervals until latter part of December.

We first saw the patient at 3 p. m., Jan. 31, 1902. About 9 o'clock that morning there occurred an attack similar to that previously described.

Her expression was anxious; she complained of severe pain, paroxysmal in character, located in right inguinal and sacral region. Pulse, 100; temperature, 99.4; respiration, 26. Chest negative. Abdomen distended. On palpation no tenderness except over an area extending transversely from right iliac spine to three inches to left of median line, and upward to a point midway between symphysis pubis and umbilicus. In this locality was felt a mass, slightly movable, regular in outline, giving a flat note on percussion. External genitalia showed usual signs of pregnancy. No hemorrhage. Bimanual examination revealed a soft cervix, not patulous, displaced forward and upward; cul-de-sac and right pelvis completely filled by a swelling, somewhat irregular on lower surface and very tender to touch. No distinct sulcus between the uterus and mass could be determined. The patient at this time was quite restless. Auscultation not attempted.

The clinical history and physical findings led to a diagnosis of extra-uterine with probably intra-uterine pregnancy.

She was taken to hospital; prepared for both abdominal and vaginal section. Under ether anesthesia, examination proved more satisfactory. The swelling seemed to be continuous with the right horn of an enlarged uterus. Incision posterior to cervix, opening of cul-de-sac and base of right broad ligament was followed by a gush of partly clotted blood; placental tissue was punctured, and a perfectly formed fetus extracted by the feet; placenta removed piecemeal. One hand in cavity now felt the womb softened and enlarged in size to that of pregnancy between the third and fourth month. While on the table patient became almost pulseless, requiring vigorous stimulation. Sterile gauze packing controlled hemorrhage. Twenty hours later, following intermittent pains and slight bleeding, a second fetus and placenta were expelled from the uterus. Packing removed on fourth day. The intra-uterine fetus measured 12 cm. from vertex to rump, the extra-uterine fetus 10 cm.

Convalescence was interrupted by a slight elevation of temperature and pulse, beginning on third day and continuing two weeks, evidently due to mild sapremia. Drainage from cavity profuse for several days. Patient sat up in bed on seventeenth day, returning home one week later, the wound having closed. Recent examination finds the uterus in good position, well involuted, freely movable; some thickening of right broad ligament.

In this instance there was a rupture of tube on lower surface; the fetus and placenta developing within the right broad ligament—a true intra-ligamentary pregnancy.

THE SURGICAL TREATMENT OF EXOPHTHALMIC GOITER.

The realm of the physician is gradually becoming more and more circumscribed. His domain, or, what he seemed reasonably justified in considering his undisputed domain, is steadily being invaded by the intrepid surgeon. Who, ten years ago, would have thought that nephritis would ever be treated by means other than medical? Chronic endocarditis would seem to be an affection that the clinician would ever claim undisputed right to treat without the aid of the surgeon. Yet Lauder Brunton, a physician and not a surgeon, as a result of experiments on dogs, advances the view that there is sufficient evidence to warrant the surgeon in incising the constricted mitral orifice in cases of advanced mitral stenosis. Who will be the venturesome surgeon to first act on this suggestion and what will be the result? We had thought that angio-neurotic edema was exclusively within the sphere of the physician. Resection of the nerve supplying the affected area has been advocated and even carried into effect with beneficial results in this or a closely allied affection.

Physicians are quite ready to concede that, up to the present time, the therapeutic treatment of exophthalmic goiter has been, on the whole, eminently unsatisfactory. Grünbaum, during the last year or two, has used the serum of thyroidectomized goats in the treatment of this disease. We shall have to await the results of more extended experience with the serum-treatment before passing judgment on it. Considering our demonstrated helplessness in securing any permanent improvement by the medical treatment of Basedow's disease in any large percentage of cases, the physician will welcome the inroad of the surgeon and the results he has obtained in this distressing disease. We are indebted to Professor Kocher of Bern for having conclusively demonstrated that surgical procedures give by far the best results ever obtained in the treatment of this affection.

Albert Kocher[1] has recently reported the cases of Basedow's disease which have come under the observation of his father, Professor Kocher, in his hospital and private practice between the years 1883 and 1899. The series comprises 93 cases, of which 74 were cases of true exophthalmic goiter. What is of especial interest in this monograph is the record of Professor Kocher's results in the operative treatment of this disease. Kocher insists that the operation should not be done when the patient is in the stage of marked cardiac and psychical irritability. Means must be used to reduce these as much as possible first. All the operations were performed under the local use of a 1 per cent. solution of cocain. Altogether, 59 of the 74 cases of true Basedow's disease were operated on.

Four of the 59 cases died with symptoms of tetany within ten days of the operation. Of the remaining 55 cases, 39, or about three-fourths, had unpleasant postoperative symptoms. These consisted of transitory psychical disturbances, irritability, oppression, palpitation, sensation of heat, congestion of the face, general tremor, sweating, vomiting, fever and irregular, frequent pulse; in fact, temporary increase in the symptoms present before the operation. The fever and tachycardia persisted in all the 39 cases. The other symptoms mentioned occurred in the majority of the patients. The possibility that these symptoms were due to an acute toxemia resulting from absorption of certain substances pressed from the gland during the operation is discussed, but a satisfactory explanation for the aggravation of the symptoms is not arrived at. The other 16 patients operated on had no disagreeable after-effects. The results of the operative treatment are satisfactory. Of the 59 cases operated on, 45, or 76 per cent., were cured; 8, or 14 per cent., were decidedly improved; 2, or 3.5 per cent., were only slightly improved; 4, or 6.7 per cent., died with symptoms of tetany after the operation.

In 15 of the 74 true Basedow cases medicinal treatment of various kinds was used. The results, notwithstanding the fact that several of them were mild cases, are in striking contrast to those obtained from operative procedures. In only one case could a cure be said to have occurred, and this was really brought about by the patient developing an intercurrent disease.

Postmortems were obtained in three of the four fatal operative cases. Several factors may have played a part in causing the fatal termination in the first case. There was a persistent thymus; the heart was dilated and there was a fluid exudate in the serous cavities, and the superior cervical ganglion was very much enlarged. In the second case death was found to be due to double-sided pneumonia and pleurisy. The fatal result in the third case was believed to be due to the extreme severity of the intoxication. At autopsy the dilated heart, spleen tumor, jaundice and fatty degeneration of the liver and spleen confirmed this view.

The profession should be familiar with Kocher's brilliant results. Clinicians will welcome the invasion of their territory when results such as these are obtained. A vigorous warning against this operation being undertaken by only the most experienced surgeons must be made, however. Only those who have had wide experience in thyroid surgery and in the local use of cocain should undertake the operation.

[1] Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie, 1902, ix, Bd., 1 u. 2 Heft.

THE SEASONAL PREVALENCE OF TYPHOID FEVER AND ITS RELATION TO SEASONAL TEMPERATURE.

The prevalence of typhoid fever at certain seasons has given rise to several explanatory hypotheses. Perhaps the most important of these, and certainly the best known, is that of Pettenkoffer, who tried to establish a relation between the level of the ground water and variations in the prevalence of typhoid. It is true, that at Munich there existed a definite relation between the level of the ground water and typhoid, but, as pointed out in the recent statistical study on temperature and typhoid fever by Sedgwick and Winslow,[1] in most cases it does seem as if the possibility of the influences of temperature had not been satisfactorily excluded. Indeed, there has been no very satisfactory explanation offered of the fact that, in some cases at least, the number of cases of typhoid fever is most abundant when the ground water is lowest, as claimed by Pettenkoffer and his school.

Sedgwick and Winslow have gathered a large mass of statistics from various parts of the world and representing a wide range of climate in order to study what relations, if any, exist between the periodical prevalence of typhoid and temperature. It seems that only few have looked for an explanation of the seasonal distribution of typhoid fever in temperature, and to most of us the fall maximum of typhoid fever has remained a more or less mysterious phenomenon. The curves of Sedgwick and Winslow show a striking parallelism between monthly variations in temperature and the prevalence of typhoid. In northern localities the maximum number of cases of typhoid occurs in September and October. In southern cities, in which there is a milder winter, most cases occur in August and July. In tropical and subtropical regions the typhoid curve rises with the temperature in the spring, falling with it in the autumn, but shows a decrease at the time of greatest heat, due, perhaps, to great dryness or the action of sunlight. In certain cities in which the curves were more or less irregular, special factors may have entered into play that would tend to upset the parallelism between the temperature curve and the typhoid curve, as, for instance, sudden epidemic outbreaks, due to infection of a number of persons at once through some common medium, like milk or water. In such instances curves based on a small number of cases are likely to show irregularities that on superficial view do not harmonize with the typical seasonal curves. In some of the cities furnishing large statistics, such as Chicago, Cincinnati and Philadelphia, the typical curves show secondary elevations, one in December or January, and one between March and May. These rises in the typhoid morbidity are traced by Sedgwick and Winslow to the facts that these cities derive their water from sources liable to surface pollution, and that autumn rains and spring floods may carry into the water supply a larger amount of pollution at these times than at others. Sedgwick and Winslow would explain the reasons for the seasonal variations in the prevalence of typhoid fever and their relations to the temperature in the following way: The bacilli of typhoid fever do not thrive outside the body during colder seasons of the year. Some germs may survive the winter within the bodies of patients, e. g., the urinary bladder, or perhaps in vaults and other depositories where they may be protected from the cold. As the season grows milder the germs that enter the outer world will stand a better and better show to live and multiply and again enter human beings. Naturally this will be a cumulative process. "Each case will cause more secondary cases, and each of the latter will have a still more extensive opportunity for widespread damage. In our opinion, the most reasonable explanation of the seasonal variations of typhoid fever is from the effect of temperature on the persistence in nature of germs which proceed from previous victims of disease."

The data brought together by Sedgwick and Winslow certainly seem to warrant the conclusion that seasonal prevalence of typhoid fever is dependent largely on the influences of temperature on the growth and persistence of the typhoid bacillus. Their study constitutes a valuable addition to our knowledge of typhoid fever. The conclusions emphasize the urgent necessity in cities to "clean up" and to abolish all unsanitary conditions in crowded tenement districts so as to limit as much as possible the chances for typhoid bacilli surviving in our environment. These measures are, of course, only of secondary importance compared with the *sine qua non* for freedom from typhoidal diseases, namely, uninfected water.

A NEW CLINICAL ENTITY.

At the meeting of the Association of American Physicians in Washington last week, Dr. Osler presented the salient features of a series of cases which seem to fall under an as yet unrecognized independent symptom complex. Not that cases of the disease have not been previously described by others, but their full significance as belonging to a new clinical entity has not been properly appreciated. The distinctive features of the cases are chronic cyanosis in connection with marked polycythemia—an increase of the red blood cells so far above the normal that the blood count averages 10,000,000, and may go as high as 12,000,000 per cubic millimeter. Notwithstanding the intense cyanosis observed in these patients, which in certain instances makes them absolutely livid in appearance, they suffer but very little, and in some cases, indeed, not at all from dyspnea. The hemoglobin value of the blood is almost proportionate to the number of red cells and runs very high, commonly above 150.

As Osler said, ordinarily when a patient walks without difficulty into a physician's office, yet is suffering from a marked degree of cyanosis, the physician thinks at once of emphysema. If the condition is evidently one of labored breathing, heart or kidney disease may be the first thought. In some rare cases advanced tuberculosis may be found as the cause of the condition. In the cases constituting the new clinical entity, however, there is no emphysema, no heart disease and only slight albuminuria. The mild renal disturbance of which this is a sign is evidently not the cause of the cyanosis, but a result of the general condition and rather functional than organic, since, as a rule, it is not accompanied by casts, or only hyaline casts, and those not in large numbers. The only other pathologic conditions that are constant in the disease are constipation and an enlarged spleen.

---

[1] Memoirs of the American Academy of Arts and Sciences, August, 1902, vol. xii, No. 5.

The cause of the affection is not clear. Usually the *history of the cases extends back over many years.* Dr. Osler's first patient was a physician, whose cyanosis had been a cause of wonder for several years before he came for professional consultation, the thought being that it was probably due to emphysema. It is well known that congenital heart disease producing the cyanotic condition called by some morbus cæruleus, or "blue disease," is most commonly accompanied by a very large increase in the number of red blood cells with a corresponding increase of hemoglobin. Eichhorst[1] refers to some cases of this kind in which the blood count was 9,000,000 and the hemoglobin value above 160 per cent. Some of these cases do not show symptoms in early life, but develop the circulatory insufficiency of their congenital heart disease only with advancing years. Of course, these cases, as suggested by Osler, are at most but analogous examples of cyanosis with polycythemia, and were referred to only as throwing a certain light on the special pathologic condition described by him. None of his patients exhibited any of the cardiac symptoms of congenital malformation, and all had lived well beyond middle life without any discomfort traceable to such a cause.

Curiously enough, after the report of Dr. Osler's cases, in which he referred to previous descriptions of like sets of symptoms in medical literature, and especially to two cases seen by Dr. Richard Cabot of Boston, a number of prominent clinicians reported similar cases that had been under their observation in recent years, though they had not realized the possibility of the independent nature of the clinical symptom complex present. These observers were from various and distant parts of the country, from Toronto, Buffalo and Boston to Los Angeles. It seems evident, then, that as soon as it is realized how definite the new affection is that many other cases will be reported. We shall expect to find in the medical literature of the near future ample confirmation of these preliminary reports. It is evident that there are many such cases in existence, and we may look for examples of this new clinical entity in abundance in the literature of the near future. The suggestion of its independent nature is likely to stimulate clinical observation to the distinct credit of American medicine.

THE REVIVAL OF THE "ST. LUKE'S HOSPITAL" FRAUD.

It is only about a couple of years ago that the notorious "St. Luke's Hospital" diploma mill and general fraud found it expedient to go out of business under special stress of Michigan laws. Now it has appeared again, under another name, it is true, but evidently under the same auspices and general control and with the same policy and fraudulent practices. Since the 15th of May the mail of THE JOURNAL has been flooded with the circulars of the "Christian Hospital," 617 La Salle Avenue, Chicago, sent to it by righteously indignant correspondents. These circulars have all the characteristics of the old St. Luke's Hospital output, the same offers of staff positions, fac similes (reduced) of diplomas, promises of advertisement and offers of commissions on cases sent. The circulars outdo the St. Luke's samples in their unauthorized use of names of prominent physicians, in some cases thinly disguised; among others they brazenly *use the name of a noted Chicago surgeon as chief of staff.*

In Michigan St. Luke's Hospital flourished under the lack of state laws properly covering the offense of fraudulent diploma selling, and not until the legislature passed an act especially meant to reach it, did the concern succumb. One "Dr." A. C. Probert, who was the real manipulator of the fraud, is also prominent in the "Christian Hospital" literature, if, indeed, he is not the real "it" of the concern. While most of his associates are new, we still see the name on the roster of Dr. Charles W. H. B. Granville, who was the figurehead of the Michigan concern, and who also figured in some legal proceedings elsewhere. The boldness of these impostors in thus coming out under their real names and following the identical methods in which they had been so clearly exposed is rather striking. They probably have reckoned on a similar deficiency in Illinois statutes as that they first profited from in Michigan, and have, it would seem, cleverly timed this initiation of their work to coincide with the end of the legislative session, expecting, therefore, to have a free hand for at least the next two years. If it should indeed so happen that no existing state statute reaches the case, it would seem that the United States postal laws ought to cover such fraudulent use of the mails by such a disreputable diploma-selling concern as well as in the Armstrong case. While we have no sympathy whatever with the medical practitioner whose idiotic egotism is gratified by sticking up such a diploma in his office on the promise of unethical advertisement and exploitation of his patients, we would be glad to see honest physicians relieved from exposure to the insult that such offers necessarily imply. We have abundant evidence that a large proportion of our readers are feeling just that way. Moreover, we want to see justice done and a stigma on the fair name of any city and state where such practices are permitted removed. The sooner the end of the "Christian Hospital" comes the better.

If any of our readers have sent the concern money and have been defrauded thereby we shall be glad to hear from them.

---

[1] Eichhorst, Pathologie und Therapie, vol. 1, p. 110 et seq., 1899.

SUPER-SUPERLATIVE FLATTERY.

We like to see the articles of THE JOURNAL quoted and fully credited, but we do not like to see our abstracts abstracted without credit; neither do we enjoy seeing the original matter taken bodily without so much as a thank you. Imitation is said to be the sincerest kind of flattery; actual appropriation must therefore be even super-superlative. Hence, we feel flattered in seeing an editorial which appeared in a recent issue of THE JOURNAL incorporated bodily, with only a *dozen or so verbal changes, into an editorial in one of* our Eastern contemporaries. We had credited the editor of the *Medical Times* with the ability to write his own editorials.

VACCINATION AND THE ANTIVACCINATIONISTS.

The antivaccinationists and anti-vivisectionists are still using the Cleveland example as a noted instance of the failure of vaccination and the advantages of disinfection against smallpox. It might be well to restate the facts, which seem to have been lost sight of by the general public. The disinfection did not abate the smallpox, but was followed by an epidemic of over 1,200 cases and over 200 deaths, and then Cleveland made up for its laxity by a most vigorous vaccination crusade, with a final result of stamping out the disease. While the anti-vaccinationists will still probably continue to ignore this, it is just as well once more to restate the facts. If there is anything positive in medicine it is that vaccination will stamp out smallpox.

THE IDENTITY OF SYSTEMIC BLASTOMYCOSIS AND THE SO-CALLED PROTOZOIC DISEASE.

American investigations concerning blastomycosis in man, and closely related or identical processes, have reached considerable proportions. This work begins with Gilchrist's description of his first case of blastomycetic dermatitis. Almost two score of similar cases have since been reported and the mycology often clearly set forth. The next important step consisted of the work of Rixford and Gilchrist on the so-called protozoic disease, their results showing the identity of the minute anatomy of the skin lesions in this disease and in blastomycetic dermatitis. However, it seems that Rixford and Gilchrist were in error in concluding that the micro-organism in the protozoic disease is a protozoon, for Ophüls and Moffit[1] demonstrated in a thorough manner that the organism is a *mold-fungus*. Another important feature is that the fungus of Ophüls and Moffitt, as nearly as one can tell from a published description, is identical with the Oidium hyphomycoide isolated by Ricketts[2] from several cases of blastomycetic dermatitis; Montgomery[3] also appears to have obtained the same organism from a similar case. The apparent identity of the organisms is strongly suggestive of the identity of the two diseases. Of interest in this connection is the report of a case of "Systemic Blastomycosis," by Ormsby and Miller,[4] the infection atrium being apparently in the lungs. Without entering into details it may be stated that the course of the disease and the autopsy findings are identical with those of certain cases of the protozoic disease. The clinical history was very similar to that of generalized tuberculosis, the autopsy disclosing small abscesses and tumor- and tubercle-like formations in visceral organs. In addition, the organism cultivated by Ormsby and Miller from their case seems identical with that of Ophüls and Moffitt. So one could say that either the Ophüls and Moffitt case was one of blastomycosis, or that of Ormsby and Miller was a case of the protozoic infection. The latter authors failed to draw attention to this probable identity in their report. Our obdurate colleagues in Germany probably will continue to consider this disease (blastomycetic dermatitis) the creation of an imaginative (American) mind, until they have succeeded in determining a case in the "Vaterland." A German critic (Kromayer) is able to recognize only one case of true blastomycetic infection in man, and that was a systemic infection described by Busse and Buschke. This position is in part due to the well-known German ignorance of scientific work in America.

Medical News.

ILLINOIS.

St. Francis' Jubilee.—The twenty-fifth anniversary of the formal opening of St. Francis' Hospital, Peoria, was formally celebrated last week.

Smallpox.—There are said to be 20 cases of smallpox at Dalton, and in default of an isolation hospital, guards have been posted at the homes where the disease exists.

Personal.—Dr. Edith Fyffe, Chicago, has returned from Europe.——Dr. Nicholas Senn, Chicago, reached New York, May 15, on his return from Madrid.——Dr. W. G. Willard, Chicago, major and surgeon Illinois National Guard, assigned First Infantry, has resigned.——Dr. Ben D. Baird has been made health officer of Galesburg.——Dr. Alfred C. Phillips, Apple River, was taken ill in New Orleans, May 6, and was removed to the Louisiana Retreat.

Chicago.

Pneumonia Deaths.—This disease caused 172 of the total 586 deaths recorded during the week ended May 16, from all diseases—excluding the 46 from suicide and violence. This was nearly one-third (29.3) per cent. Since the first of the year there have been 2,659 deaths from pneumonia and 1,190 from consumption, or nearly 125 per cent. more from pneumonia.

Increased Requirements.—Rush Medical College, beginning with this summer, will demand 12 majors, in addition to a four years' high school course; one-half of these must be in special preparatory studies for medicine and must include chemistry and elementary biology. In June, 1904, the requirements will be further increased and a year later the completion of the junior college course or its equivalent will be required.

Old Milk and Infant Mortality.—The health department reports 184 deaths of children under 5 years of age during last week, as against 138 during the previous week—an increase of exactly one-third, 33.3 per cent.; and as against 128 in the corresponding week last year—an increase of 43.7 per cent. The length of time between the drawing of milk and its delivery and use is considered a cause. Thousands can not afford ice and preservatives will add to the injuriousness of the milk. The Bulletin of the health department refers to the great improvement in milk quality in the past six years and the lessened death-rate among infants and urges continued enforcement of regulations looking toward pure milk.

IOWA.

New Graduates.—Keokuk Medical College, at its sixty-sixth annual commencement, April 28, conferred degrees on a class of 56.

Personal.—Dr. David S. Fairchild, formerly of Clinton, has removed to Des Moines and has been appointed dean of the medical department of Drake University.

[2] Jour. of the Boston Soc. of Med. Sciences, 1901, v, 453.

[3] JOURNAL A. M. A., 1902, xxviii, 1486.

[4] The Journ. of Cutaneous Diseases, March, 1903.

Itinerant Abandons Fight.—"Dr." B. P. Rea, an itinerant medicine man who was indicted a year ago for practicing without license and was fined $300 and costs, gave notice of appeal and threatened to demonstrate the unconstitutionality of the law under which he was convicted, by carrying the case to the Supreme Court. Wiser counsels have prevailed, however, and he has now paid the fine and costs, amounting to about $318.

MARYLAND.

Baltimore.

Want Good Milk.—The new Baltimore Pediatric Club held a meeting, May 21, to launch a crusade for better milk. Addresses were made by Dr. Henry L. Coit of Newark, N. J., and by Drs. Osler, C. W. Mitchell, C. Hampson Jones and Bassett of Baltimore.

The mortality for the week was low, 165, being 15.90 per 1,000, and for the whites only 13.72. Pneumonia caused a large proportion of deaths, 19, being exceeded by consumption by but one. Seven new cases of smallpox were reported and 33 of scarlet fever.

MASSACHUSETTS.

Appointments.—At the Boston City Hospital, Dr. John N. Coolidge has been appointed medical registrar, and Dr. George A. Leland, visiting aural surgeon.

Bequests.—John L. Day, Quincy, left $5,000 to the Quincy Hospital, and the same amount to the Carney Hospital, Boston, and to St. Mary's Infant Asylum.

Death and Infection.—For the week ending May 9 210 deaths occurred, equivalent to an annual death-rate of 18.68 per 1,000. Pneumonia caused 30; whooping cough, 5; heart disease, 22; bronchitis, 6; tuberculosis, 29; diphtheria, 4, and violence, 12 deaths. Of infectious diseases there were reported: diphtheria, 40 cases; scarlet fever, 33; typhoid fever, 16; measles, 31, and tuberculosis, 25.

Tuberculosis Increasing Among Hebrews.—The United Hebrew Benevolent Society, Boston, has discovered that tuberculosis is rapidly increasing among the Hebrews of Boston. The society is taking active measures for bettering the crowded conditions in the midst of which many Hebrews live, and to which the spread of this disease is attributed. Six of the 17 cases reported to them this last year were sent to the Hebrew Hospital in Denver.

Boston.

Boston's mortality for the week ending May 15 was 20.37. The largest elements were pneumonia, 39; heart disease, 26; tuberculosis, 26; diphtheria, 6; bronchitis, 5. The prevalence of contagious diseases is indicated by the report of 38 new cases of diphtheria, 45 of scarlet fever, 18 of typhoid fever and 53 of measles.

Report on Insane.—The trustees of the Boston Insane Hospital report that they have under their care 1,771 patients, of whom only 543 are in the institution directly under their supervision. Several new buildings are being constructed to relieve the crowding here, but the provision is far from sufficient. They urge the great injustice of compelling relatives and friends to travel the long distances necessary to get to the state institutions which are themselves far too much crowded. The net cost per week per patient was $4.05.

MISSOURI.

Baker Retains License.—On April 27 the State Board of Health decided that the charges against Dr. Charles M. Baker of Santa Fe were not well enough founded to justify taking away his license. He was, therefore, exonerated.

Examining Board.—At the session of the State Board of Medical Examiners in Kansas City, April 28, one candidate appeared, was rejected, and the board adjourned. At the previous session, April 1, the board examined 21 applicants.

Medical Student Commits Suicide.—Gaston M. Jordan, Caruthersville, a junior student at Memphis (Tenn.) Hospital Medical College, despondent over his failure to pass the senior grade examinations, committed suicide, April 30, by taking two ounces of chloral.

Leper Found in Laundry.—Dong Gong, the Chinese leper of St. Louis, of great notoriety, who escaped from quarantine two days before, was captured, May 7, in a Chinese laundry. Patrons of the laundry were in great alarm and in many cases are said to have made bonfires of the clothing washed there. The proprietor has been compelled to leave the neighborhood.

NEW YORK.

Graduation Exercises.—The seventy-second annual commencement exercises at Albany Medical College were held May 5, when 34 young physicians received diplomas from Chancellor Van Vranken of Union University.

The Ithaca Epidemic.—Dr. George Soper of the State Board of Health reports on the Ithaca epidemic that "so far as can be said at present, there have been 955 cases and 64 deaths. This ranks the epidemic among the most important in modern times in this part of the world." Twenty-nine of the deaths were of Cornell students.

Grip, Pneumonia and Nephritis.—The bulletin of the State Board of Health for March says that the state is at present in the course of an annually recurring epidemic of grip. A few deaths were reported as early as October, but the estimated mortality was not above 500 until January, when it was placed at 1,200 for the month, and for February it was increased to 1,500. The mortality of March was increased 2,000 by this disease. Separate record has not been kept of pneumonia save for the past two years. It was the cause of 8,800 deaths in 1902, or a little over 50 per cent. of the reported acute respiratory mortality. In January there were 1,223 deaths, in February 1,133, in March 1,290. Nephritis caused 726 deaths in March, a decrease from last month.

Buffalo.

Bond Issue Authorized.—The state legislature has passed a law granting Buffalo the privilege of issuing bonds for $500,000 for the improvement and extension of the water system.

Personal.—Dr. Charles G. Stockton went to New York to attend the dinner given by Dr. Max Einhorn in honor of Professor Ewald of Berlin.——Dr. Irving P. Lyon is in the Adirondacks.——Dr. Harvey R. Gaylord of the Gratwick Cancer Laboratory has typhoid fever.

Hospital Appointments.—Drs. Edward Drozeski, Hyatt Regester, Thew Wright and Fred Parmenter have been appointed resident physicians at the Buffalo General Hospital.——Drs. Elliott Bush, C. J. Roberts and Albert Bixby have been appointed resident physicians at the Erie County Hospital.

PENNSYLVANIA.

To Lessen Child Labor.—A bill passed by the legislature raising the age limit of children employed in the coal mines from 14 to 16 has been approved by the governor.

Food Laws Violated.—Dairy and Food Commissioner Warren has ordered 24 prosecutions in various parts of the state for violations of the laws relating to dairy and food products. Of this number 14 are in Allegheny.

Philadelphia.

John Herr Musser.—In the account of the new President of the American Medical Association in THE JOURNAL, May 16, his name was given as John Henry Musser. It should have been John Herr Musser.

Anthrax has appeared among a herd of 50 cows on the dairy farm of Albert Zimmerman in the outskirts of the city. The Bureau of Milk Inspection has placed the farm under quarantine and has ordered an inspection of all the dairy farms near the city.

Playgrounds.—The grounds of 35 public schools in different parts of the city will be opened by the board of education on July 1, for a period of two months, as playgrounds for children. Kindergarten teachers are appointed to direct the children at play, at a salary of $40 per month each.

Death and Disease Report.—There were 474 deaths in Philadelphia for the week ended May 16, as against 396 for the corresponding week of last year. Of diphtheria there were 64 new cases and 7 deaths; scarlet fever 93 new cases, 3 deaths; typhoid 247 cases, 27 deaths; smallpox 30 cases, 1 death.

Sweatshop Crusade.—Local factory inspectors have begun an active crusade against manufacturers of clothing whose employes are compelled to work in unsanitary shops. Investigation has shown that young women and girls are compelled to work in crowded quarters without regard to sanitary precautions, and also that many of these sweatshop employes are under the age limit of 13. Warrants have been issued for the arrest of several employers.

Medical Club Reception.—On the evening of May 15 the Medical Club, several hundred in number, gave a reception at the Hotel Bellevue in honor of Prof. J. von Mikulicz-Radecki of Breslau, Prof. C. A. Ewald of Berlin, Prof. Hans Kehr of

Holberstadt, Prof. Hermann Tillmans of Leipsic, Mr. Moynihan of Leeds, England, Professor Adami of Montreal, and Dr. George H. Simmons of Chicago. The guests of honor all spoke earnestly of the courtesies shown them on the occasion, the foreign visitors especially of the hospitality lavished on them throughout their stay in America. The reception was preceded by a dinner at the University Club, at which Dr. E. E. Montgomery, president of the Medical Club, was the host.

The New Director of Health.—The mayor has appointed, as the director of the new Department of Public Health and Charities, Dr. Edward Martin. Dr. Martin was born in Philadelphia in 1859. He received A.B. and A.M. degrees from Swarthmore College, and was graduated from the medical department of the University of Pennsylvania in 1883. He is professor of clinical surgery at the University of Pennsylvania and surgeon at the Howard, St. Agnes', Philadelphia and University hospitals. He was surgeon of the Third Regiment in the Spanish-American War, was appointed brigade surgeon by President McKinley, and was afterward made sanitary inspector of the Fourth Army Corps. Dr. Martin has written several medical text-books and has made other contributions to medical literature. Dr. Martin has appointed as chief of the bureau of health, Dr. A. C. Abbott, professor of hygiene at the University of Pennsylvania; as chief resident physician of the Philadelphia Hospital, to succeed the late Dr. Daniel E. Hughes, Dr. Montgomery H. Biggs, formerly chief resident physician of the University of Pennsylvania Hospital. The following eminent physicians are invited to act as a consulting board to the department: Dr. S. Weir Mitchell, J. William White and John H. Musser of the University of Pennsylvania; Dr. Charles B. Penrose of the Gynecean Hospital; Dr. Hobart A. Hare of the Jefferson Medical College, and Dr. J. M. Anders of the Medico-Chirurgical College. Dr. Martin's ability and the high character of his appointments inspire the belief that his administration marks a new era in the sanitary regulations of Philadelphia, in the conduct of the Philadelphia Hospital, and in all that pertains to the health of the city.

GENERAL.

Navy Stops Recruiting.—Because of overcrowded conditions and some contagious diseases on receiving ships, the naval department has ordered all recruiting stopped till further notice. The present enlisted force is within about 2,000 of the maximum allowed by law, 31,000.

Marine-Hospital Appointments.—Examination for the positions of assistant surgeon of the U. S. P. H. and M.-H. S. will be held June 15 at Washington. Candidates must be between 22 and 30 years of age, and graduates of reputable medical colleges. The test is partially in writing on the usual medical subjects and partially clinical, at a hospital. Further information may be had of Dr. Walter Wyman, surgeon-general, Washington, D. C.

FOREIGN.

Measles in Fiji.—A severe epidemic of measles is reported in the Fiji Islands.

The Peru plague outbreak seems at present to be at an end. Some have expressed doubts as to its having been plague at all.

Mazatlan Uses Oil Against Plague.—To prevent another outbreak, Mazatlan authorities are using petroleum on streets and houses to ensure the death of all plague germs that may remain.

Further Research on Malaria in the Congo.—The king of Belgium has sent $2,500 to the Liverpool School of Tropical Medicine to be devoted to the study of malaria in the Congo region.

Recrudescence of the Plague.—An exchange quotes the following figures to show the spread of the plague in India. During the month of February, 1899, the total deaths from plague throughout India were 12,000. During the same month in 1900 the figure was 11,000; in 1901, 34,000; in 1902, 86,000, and in 1903, 112,000.

Correspondence.

Fraudulent Use of Dr. Murphy's Name.

Chicago, May 19, 1903.

To the Editor:—I received your letter to-day with the literature from the "Christian Hospital" inclosed. I would say that your letter was one of hundreds which I have received, containing the same kind of literature. As far as I am able to determine, all of the states west of the Mississippi have been flooded with the publications of the "Christian Hospital." I would say, further, that my name was used without either my knowledge or consent, and that this literature was sent out during my absence from the city. I do not know, and have never seen, to my knowledge, a single man whose name is mentioned in the list of the "staff"; I see in there a number of the names which were used in a scheme similar to this one in connection with the "St. Luke's Hospital, Niles, Michigan," scheme, where Dr. Senn's name was used, and also one in which the name of Dr. E. O. Kinsman of Cambridge, Mass., was used in a similar way. J. B. Murphy.

Deaths.

John P. Bryson, M.D. Humboldt Medical College, St. Louis, 1868, professor of genito-urinary surgery in the medical department of Washington University, died at his home in St. Louis, May 5, from heart disease, after an illness of five days, aged 57.

Israel Pattison, M.D. University of Buffalo, 1867, for many years surgeon of the Great Western Railway, at Oelwein, Iowa, died at his home in that place, April 26, from brain disease, after an illness of two weeks, aged 62.

William J. Burgess, M.D. University of St. Louis, Mo., 1847, died at Quincy, Ill., April 7.

Deaths Abroad.

J. B. V. Laborde, M.D., Paris, 1864, director of the physiologic department and of the laboratory of anthropology, inspector of the private sanatoria of the Seine, editor of the "Tribune Médicale" for thirty years and president of the French Association of the Medical Press, died at Paris, April 5, aged 73. Among his numerous contributions to science are various works on physiology, on chloroform, intoxication with different poisons and extensive research on the application of the experimental method to the study of biology. He has lately been a leader in the campaign against the use of white lead and the abuse of alcohol. His world-wide fame, however, rests on his method of resuscitation of the apparently dead from drowning, poisoning with gas, etc., by rhythmic tractions of the tongue. As the "Gazette Medicale de Paris" remarks, "this was a true discovery, by a true scientist, and popularized by a true journalist."

Medical Organization.

Reorganization in Texas.

The Texas State Medical Association met in San Antonio, April 28-30. At the meeting in 1902 the committee appointed at the previous annual meeting to consider and report on a new plan of organization had failed to agree, presenting a majority and minority report, both more or less at variance with the Association plan. A little feeling was engendered in discussing these reports, but this had disappeared during the year, and even before the session was called to order it was evident that a spirit of harmony and unity was in the air. Much of this good feeling was due to the peace-making work of the San Antonio District Medical Society, and similar efforts on the part of the medical journals of the state, and of individual members.

At the first meeting the subject of reorganization was referred to a large committee composed of one delegate from each county represented. After patiently going over the constitutions and by-laws proposed by the American Medical Association for both state and county societies, section by section, this committee reported unanimously in favor of the uniform plan without change, and it was adopted without a dissenting voice, with genuine enthusiasm.

Texas has 270 counties and about 6,000 physicians. The state was divided into fifteen districts, with councilors in each as follows:

First District, S. T. Turner, El Paso; Second, P. C. Coleman, Colorado; Third, D. P. Fly, Amarillo; Fourth, C. M. Alexander, Coleman; Fifth, W. B. Russ, San Antonio; Sixth, A. E. Spohn, Corpus Christi; Seventh, T. B. Bennett, Austin; Eighth, Walter Shropshire, Yoakum; Ninth, J. T. Moore, Galveston; Tenth, B. F. Calhoun, Beaumont; Eleventh, R. S. Burroughs, Buffalo; Twelfth, W. R. Blailock, McGregor; Thirteenth, J. H. McCracken, Mineral Wells; Fourteenth, C. E. Cantrell, Greenville; and Fifteenth, Holman Taylor, Marshall.

Under a special resolution the council was appointed by the president to serve for one year, when the new house of delegates will elect regularly. The council organized promptly, electing J. T. Moore of Galveston chairman and W. B. Russ of San Antonio secretary, and after full discussion mapped out an active campaign for the year. On the recommendation of the council the secretary of the association was instructed to have 5,000 copies each of the constitution and by-laws for state and county societies printed for free distribution to the profession of the state, and he was authorized to issue charters to county societies until the next annual meeting, on recommendation of the council. It was also provided that new members of county societies joining between now and the next annual meeting who pay their state dues in advance, shall have credit for such dues for 1904, practically obtaining membership for two years by paying for one year. Texas has an unusually strong and progressive medical profession. Its new practice act is just being put into operation, and with the new organization, which has the promise of united support from every section, it can and ought to lead in every helpful reform in which it takes an interest.

The following officers were elected: President, Dr. Frank Paschal, San Antonio; vice-presidents, Drs. Ferdinand E. Daniel, Austin, Alfred L. Hathcock, Palestine, and Joseph D. Becton, Greenville, and orator, Dr. Henry A. Barr, Beaumont.

J. N. McCormack.

Societies.

COMING MEETINGS.

South Dakota State Medical Society, Mitchell, May 27-28.
Connecticut Medical Society, Hartford, May 27-28.
West Virginia State Medical Association, Charleston, May 26-28.
Indian Territory Medical Association, South McAlester, June 2-3.
Medical Society of the State of North Carolina, Hot Springs, June 2.
Ohio State Medical Society, Dayton, June 3-5.
Rhode Island Medical Society, Providence, June 4.
Wisconsin State Medical Society, Milwaukee, June 3-5.
Maine Medical Association, Portland, June 3-5.
Indiana State Medical Society, Richmond, June 4-5.
Medical Society of Delaware, Dover, June 9.
Massachusetts Medical Society, Boston, June 9-10.
Michigan State Medical Society, Detroit, June 11-12.
Minnesota State Medical Society, St. Paul, June 17.
Medical Association of Montana, Helena, June 17-18.
Medical Society of New Jersey, Asbury Park, June 23-25.

Kansas Medical Society.—At the thirty-seventh annual meeting held in Concordia, May 6, 7 and 8, the following officers were elected: Dr. William E. McVey, Topeka, president; Drs. George W. Coffey, Concordia, and John T. Axtell, Newton, vice-presidents; Dr. Clarence C. Goddard, Leavenworth, corresponding secretary; Dr. Lewis H. Munn, Topeka, treasurer; and Dr. Samuel G. Stewart, Topeka, librarian. Topeka was selected as meeting-place for 1904.

Medical Association of the State of Alabama.—The annual meeting was held in Talladega April 21 and 22. The report of the secretary showed that 1,225 physicians of the state were members of the county societies, and that the remaining 773 were non-members. Dr. Matthew B. Cameron, Sumterville, was elected president; Dr. John R. G. Howell, Dothan, vice-president southern district; Dr. Lewis C. Morris, Birmingham, secretary; Dr. Henry G. Perry, Greensboro, treasurer, and Dr. George S. Brown, Birmingham, orator. The association will meet in Mobile in 1904.

AMERICAN GYNECOLOGICAL SOCIETY.

Twenty-Eighth Annual Meeting, held in Washington, D. C., May 12 to 14, 1903.

The President, Dr. Joseph E. Janvrin, New York, in the Chair.

An address of welcome was delivered by Dr. I. S. Stone of Washington, D. C., which was responded to by the president.

There was a symposium on the following subject:

What Shall Be the Treatment in Cases of Pregnancy Complicated by Fibroid Tumor?

The first paper, with this title, was read by Dr. Henry C. Coe, New York, who stated that fibroid tumors complicate pregnancy because they interfere with the normal development of the pregnant uterus. They cause distressing symptoms, or they jeopardize the life of the fetus or of the mother. Each case must be studied separately, and the decision as to the treatment will vary with the patient, the tumor, the experience, and bias of the surgeon. He spoke of the influence of the tumor on pregnancy, and of pregnancy on the tumor—increased growth, degenerative changes, environment, etc. He mentioned three "semesters" of pregnancy:

1. Up to the fourth month. (a) Empty the uterus in the case of large interstitial or broad ligament tumors, or where they are situated in the lower uterine segment. Also in cases of impacted intrapelvic growths. Cases were cited in point. (b) Small tumors should be enucleated per vaginam, if possible, though pregnancy will usually be interrupted. Intrauterine polypi should be removed, if accessible. (c) Enucleation should be done by the abdominal route. Subperitoneal pedunculated growths should be removed. (d) Impacted growths should be liberated under anesthesia, when no adhesions are present, and they should be kept out of the pelvic cavity until they are kept out of the way by the growing fetus. The wishes of the patient should be followed, so far as this can be done with safety.

2. Fourth to seventh month. The location of the tumor is important, as well as its size and variety. Pain and pressure symptoms furnish indications for treatment. (a) Large interstitial growths. The uterus may be emptied, although the danger of hemorrhage from such a course is greater. (b) He advises enucleation by the abdominal route, and spoke of the propriety of removing multiple small tumors which do not encroach on the uterine cavity. (c) the patient should be kept under observation. The patient may go to full term and be delivered normally. (d) Impacted tumors, pressing on the bladder, bowel, ureter, may call for radical operation. (e) Twisted pedicle, degeneration of tumor, disease of the adnexa, peritonitis, etc., may require interference without reference to pregnancy.

3. After sixth month. Viability of the fetus should be obtained, if the life of the mother is not actually jeopardized. Can the woman be delivered at term? Yes (a) with subperitoneal growths, if they are not too large, and favorably situated. (b) Small interstitial fibroids, if they are not in the lower uterine segment. (c) Polypi presenting at the os can be easily removed at any time. After the eighth month the Porro-cesarean operation, suprapubic amputation or hysterectomy should be performed, preferably by election, i. e., before full term.

Conservatism should be practiced here, as in other gynecological operations, but not carried to extremes.

The author discussed the question of marriage and subsequent risks of pregnancy in women with fibroids. He said the time for conservative surgery is often before there is a chance of conception. In general, if a fibroid is to be regarded as a menace to life before pregnancy, the condition must be still more grave after conception occurs. Is it not the duty of the gynecologist to ward off this danger?

Officers for the Ensuing Year.

The following officers were elected: President, Dr. Edward Reynolds, Boston, Mass.; vice-presidents, Drs. J. Whitridge Williams, Baltimore, and Edward P. Davis, Philadelphia; secretary, Dr. J. Riddle Goffe, New York (re-elected); treasurer, Dr. J. Montgomery Baldy, Philadelphia (re-elected). The next session will be in Boston, May 24 to 26, 1904.

Only a small portion of the report of this society is given this week, because of the space given to the minutes of the American Medical Association session.

(To be continued.)

AMERICAN MEDICAL ASSOCIATION.

Proceedings of the Fifty-fourth Annual Session, held at New Orleans, May 5, 6, 7 and 8, 1903.

Correction to Minutes of House of Delegates.

The following correction in the minutes, as published in THE JOURNAL last week, must be made. On p. 1378, under the heading, "Dental and Pharmaceutic Members Provided For," it should have been stated that a by-law was adopted, which was worded as follows, and which will be incorporated in the Constitution and By-laws in the future:

> Dental and pharmaceutic members shall enjoy the same privileges as regular members and be subject to the same conditions.

OFFICIAL MINUTES OF THE SECTIONS.

As Rendered by the Respective Secretaries or Stenographers.

Section on Practice of Medicine.

TUESDAY, MAY 5.

Address of the Chairman, W. S. Thayer, Baltimore.

"Restorative Influence of Ozone on the Blood." G. Lenox Curtis. Discussed by F. A. Weber, Milwaukee.

"The Boy's Venereal Peril." Ferd. C. Valentine, New York. Discussion by J. J. Walsh, New York; F. W. Robbin, Michigan; DeLancey Rochester, Buffalo, N. Y.; Theodore Potter, Indianapolis; M. M. Smith, Texas; Frank A. Jones, Memphis; E. L. Stevens, Iowa; W. Shropshire, Texas, and Ferd. C. Valentine.

"Continued Fever, Neither Malarial nor Typhoid; a Clinical Study." T. J. Happel, Trenton, Tenn.

"Southern Fevers." William Krauss, Memphis, Tenn.

"Clinical Observation of Ninety Cases of Typhoid Fever, with Four Deaths, with Special Reference to Therapeutic Fasting." R. M. Harbin, Rome, Ga.

"Typhoid Fever at High Altitudes, with a Résumé of 600 Cases." J. N. Hall, Denver.

Discussion on the above four papers by T. B. Futcher, Baltimore; James Tyson, Philadelphia; J. A. Witherspoon, Nashville, Tenn.; C. F. Mason, U. S. A.; R. W. Lindson, Little Rock, Ark. Discussion of last four papers to be continued with the Symposium on Typhoid Fever on Thursday morning.

The Committee on Nominations was announced as J. H. Musser, Philadelphia; William Krauss, Memphis, and Thomas McCrae, Baltimore.

WEDNESDAY, MAY 6.

"Weakness and Dilatation of the Heart Due to Chronic Nutritional Diseases." G. W. McCaskey, Fort Wayne, Ind. No discussion.

"Limitations of Non-Surgical Treatment in Intestinal Obstruction." J. R. Eastman, Indianapolis. No discussion.

"The Occurrence of Strongyloides Intestinalis in the United States." M. L. Price, Baltimore. Discussion by C. W. Stiles, Washington, D. C.; A. J. Smith, Galveston, Texas; Ohlmacher, Ohio, and J. T. Moore, Galveston, Texas.

"Clinical Diagnosis of Intestinal Parasites." C. W. Stiles, Washington, D. C.

"Uncinariasis in the United States, with Especial Reference to Its Occurrence in Texas." Allen J. Smith, Galveston, Texas.

"Treatment of Uncinariasis." T. A. Claytor, Washington, D. C.

Discussion on the last three papers by W. G. Harrison, Alabama; E. D. Bondurant, Mobile, Ala.; C. A. Moore, Alabama; G. W. McCaskey, Fort Wayne, Ind.; T. A. Williams, Edinburgh, Scotland; Claud A. Smith, Atlanta, Ga.; James B. Herrick, Chicago; William Britt Burns, Memphis, Tenn.; C. W. Stiles, Washington, D. C.; A. J. Smith, Galveston, Texas, and T. A. Claytor, Washington, D. C.

"Bacillary Dysentery." C. F. Mason, Fort Sam Houston, Texas.

"Contribution to the Study of the Summer Diarrheas of Infancy." J. Mason Knox, Baltimore.

"Malarial Dysentery." William Britt Burns, Memphis, Tenn.

"The Clinical History and Pathology of Amebic Dysentery." H. F. Harris, Atlanta, Ga.

"A Study of the Cases of Amebic Dysentery Occurring at the Johns Hopkins Hospital." T. B. Futcher, Baltimore.

"The Treatment of Acute Dysentery." J. M. Anders, Philadelphia.

Discussion on the above six papers by Alexander Lambert, New York; T. B. Dabney, New Orleans; J. T. Moore, Galveston, Texas; W. Shropshire, Yoakum, Texas; C. F. Mason, Fort Sam Houston, Texas; J. H. Mason Knox, Baltimore; William Britt Burns, Memphis, Tenn.; H. F. Harris, Atlanta, Ga.; T. B. Futcher, Baltimore; J. M. Anders, Philadelphia.

"Abdominal Pain in Pleurisy and Pneumonia." James B. Herrick, Chicago. Discussion by J. N. Hall, Denver; T. McCrae, Baltimore; J. M. Anders, Philadelphia; B. W. Sibley, Chicago, and J. B. Herrick, Chicago.

"Traumatic Pneumonia." W. T. English, Pittsburg, Pa.

THURSDAY, MAY 7.

COMBINED MEETINGS WITH SECTION ON HYGIENE AND SANITARY SCIENCE.

"The Sources and Manner of Infection of Typhoid Fever." William H. Welch, Baltimore.

"Prophylaxis of Typhoid Fever." John S. Fulton, Baltimore.

Discussion on the above two papers by John H. Musser, Philadelphia; DeLancey Rochester, Buffalo, N. Y.; William Krauss, Memphis; Frank Warner, Ohio; J. N. Hurty, Indianapolis; Sewell, Denver; E. J. Roberts, Nashville, Tenn.; C. F. Adams, New Jersey; James Tyson, Philadelphia; J. J. Walsh, New York; Walter Shropshire, Texas; T. J. Happell, Trenton, Tenn., and John S. Fulton, Baltimore.

"The Mode of Transmission of Yellow Fever." James Carroll, U. S. A. Discussion by Stanford E. Chaillé, Edmond Souchon, Q. Kohnke and Felix Formento, New Orleans; C. W. Stiles, Washington, D. C., and James Carroll, U. S. A.

The following officers were elected: Chairman, Alexander Lambert, New York; secretary, J. S. Miller, Chicago.

"Sources and Manner of Infection of Plague." W. J. Calvert, St. Louis.

"Prophylaxis of Plague." J. J. Kinyoun, Philadelphia.

Discussion on the two above papers by F. G. Novy, Ann Arbor, Mich.; E. Richford, San Francisco, and W. J. Calvert, St. Louis.

"Arthritis Deformans." Thomas McCrae, Baltimore. Discussion by J. J. Walsh, New York; J. T. Moore, Galveston, Texas; E. E. Skinner, New Haven, and Thomas McCrae, Baltimore.

"Albuminuria in Diabetes; Its Etiology and Importance as a Factor in the Production of Diabetic Coma." Arthur R. Elliott, Chicago. Discussed by William Krauss, Memphis, Tenn.; F. R. Weber, Milwaukee, and Elliott, Chicago.

FRIDAY, MAY 8.

A committee to appoint a member to the House of Delegates was named as follows: H. L. Sullivan, Mississippi; William Krauss, Tennessee, and T. B. Futcher, Maryland. They reported in favor of Frank A. Jones, Tennessee.

"The *Passing of Chronic Rheumatism*." J. J. Walsh, New York. Discussion by James Tyson, Philadelphia; Thomas McCrae, Baltimore; Alexander Lambert and J. J. Walsh, New York.

"Hemoglobinuric Fever; Its Cause and Treatment." Walter Shropshire, Yoakum, Texas. Discussion by William Krauss, Memphis, Tenn.; Barnes, Louisiana; Frank A. Jones, Memphis, Tenn.; Southerland, Mississippi; L. A. Jabra, Tennessee; James B. McElroy, Mississippi; W. S. Thayer, Baltimore; Williams, Edinburgh, Scotland, and Walter Shropshire, Texas.

"Some Clinical Aspects of Tubercular Peritonitis." Joseph Eichberg, Cincinnati. No discussion.

"Tuberculosis in the Negro." Seale Harris, Union Springs, Ala. No discussion.

"Should the Tuberculosis Patient Know the Truth Regarding His Condition?" C. P. Ambler, Ashville, N. C. No discussion.

Adjourned.

Section on Obstetrics and Diseases of Women.

TUESDAY, MAY 5—AFTERNOON.

Meeting called to order at 2 p. m. by the Chairman, A. Palmer Dudley.

L. H. Dunning took the Chair while the Chairman read his address entitled "The Trend of Gynecological Work To-day."

On motion a vote of thanks was extended to the chairman for his very able paper.

On motion of F. Lawrence a committee of three was appointed to draft a suitable memorial on the death of W. E. B. Davis. The Chair appointed Drs. Lawrence, Cordier, Rogers, Carstens,

H. P. Newman followed with a paper on "Appendicitis from the Standpoint of the Gynecologist." Discussed by Reynolds, E. Ricketts, Wathen, Michinard, Manton, Bacon, Carstens, Thienhaus, Bovée, Massey, Lewis, McCollum, Lawrence, Craig.

"Gastric Ulcer, Some Clinical, Pathologic and Surgical Phases of," was the title of a paper read by A. H. Cordier. Discussed by J. H. Carstens, Clark, Thienhaus, Lawrence, Cordier.

On motion of Dr. Bonifield the papers of Drs. Haggard and Ricketts are to be called for the first thing in the morning session and in the event of absence of essayists, the papers are to be placed at the end of the list.

The Chair appointed the following Nominating Committee: H. P. Newman, J. H. Carstens, Lewis, H. O. Pantzer, J. G. Clark.

WEDNESDAY MAY 6—MORNING.

The Section met at 9 a. m. and was called to order by the Chairman, A. Palmer Dudley.

The first paper, entitled "Infected Gall Bladder Contents, with or without Gallstones," was read by Edwin Ricketts. Discussed by L. H. Dunning, C. V. Thienhaus, Thompson, Halderman, H. O. Marcy, A. Palmer Dudley, Ricketts.

H. O. Marcy read a paper on "The Better Methods for the Repair of the Perineal Structures." Discussed by Drs. Goelet, Dunsmore, Hayden, Graham, Gibbons, Dorsett, Carstens, Dudley, Marcy.

"The Repair of Cystocele by Utilization of the Anatomic Attachments of the Anterior Vaginal Wall" was the title of a paper read by E. Reynolds. Discussed by H. O. Marcy, Thienhaus, Bovée, and Reynolds in closing.

"Lacerations of Cervix" was the title of a paper read by Daniel H. Craig. Discussed by G. B. Massey, R. W. Holmes, Hayden, Bacon, Dunsmore, Craig.

J. H. Carstens read a paper entitled "The Hygiene of Young Girls."

F. Lawrence followed with a paper on "Pelvic Diseases in Young Girls."

Both the above papers were discussed by L. S. McMurtry, Graham, Massey, Bonifield, Carstens and Lawrence.

WEDNESDAY, MAY 6—AFTERNOON.

Meeting was called to order at 2 p. m. by the Chairman.

C. S. Bacon presented the following resolution:

"*Resolved*, That the officers of this Section be instructed to arrange future programs so far as possible for an equality both in number and arrangement of obstetric and of gynecologic papers." On motion discussion of this resolution was deferred until the afternoon session, Thursday.

A. H. Goelet followed with a paper on "Fixation of the Prolapsed Kidney." Discussed by Drs. Wagner, Dunning, Ricketts, Clark, Bonifield, Craig, Goelet.

J. G. Clark read a paper entitled "A Combined Clinical and Laboratory Study of the Effects of Peritoneal Saline Infusions in Abdominal Operations." Discussed by Drs. Bovée, Stacey, Lawrence, Bonifield, Ricketts, Thienhaus, Showalter (?), Wagner, Clark.

L. H. Dunning read a paper on "Retroversion of the Uterus; A Clinical Study of the Symptoms, Complications and Treatment."

J. Wesley Bovée contributed a paper entitled "A Further Report on Operations on the Utero-Sacral and Round Ligaments for Retroversion of the Uterus."

Discussion on these papers was participated in by Drs. Massey, Lewis, Dorsett, Milliken, Thienhaus, Carstens, Showalter, Marcy, Ricketts, Lawrence, Hall, Dudley, Dunning and Bovée.

Thursday, May 7—Morning.

Section called to order at 9:30 a. m. by the Chairman.

The first paper read was that of T. S. Cullen, entitled "Sarcomatous Degeneration of Myomata." Discussed by J. G. Clark, L. H. Dunning, C. O. Thienhaus, C. L. Bonifield, Cullen.

O. G. Pfaff followed with a paper on "Ectopic Gestation; Imbibited Tubal Peristalsis a Cause. Report of a Case with Remarks." Discussed by L. H. Dunning, H. Ehrenfest, G. B. Massey, J. H. Carstens, F. Lawrence, C. O. Thienhaus, A. P. Dudley, T. J. Beattie and Pfaff.

R. W. Holmes read a paper entitled "Non-Absorbent Gauze; The Proper Material for Tamponades for Hemorrhage, with Special Reference to Obstetrics." Discussed by C. S. Bacon, C. O. Thienhaus, Showalter, H. Ehrenfest, W. P. Manton, S. C. Gordon, H. J. Stacey, Pierce, R. Wier, E. V. Davis, G. N. Ryan, Showalter, Holmes.

Wm. P. Manton read a paper entitled "Acute General Staphylococcus Infection Through the Puerperal Breast." Discussed by Drs. Jamiston, C. S. Bacon, E. V. Davis, R. W. Holmes, Wm. P. Manton.

Thursday, May 7—Afternoon.

Section called to order at 2:30 p. m. by the Chairman.

H. P. Newman, Chairman of Nominating Committee, reported as follows: Chairman, L. H. Dunning, Indianapolis; secretary, C. L. Bonifield, Cincinnati; delegate, Wm. P. Manton, Detroit. Report was adopted on motion.

Dr. Bacon's resolution was taken up for consideration. Discussed by Drs. Ricketts, Carstens and Bacon. On motion the resolution was laid on the table indefinitely.

G. B. Massey read the first paper, entitled "Destructive Sterilization by Cataphoresis in Cancer of the Uterine Cervix." Discussed by Drs. Hayden, Moody, Pierce, Massey.

C. O. Thienhaus read a paper on "Advisability of Vaginal Exploratory Puncture and Celiotomy in Doubtful Diagnosis in Diseases of Female Genital Organs, with Cases." Discussed by Drs. Stacey, Craig, Carstens, Thienhaus.

H. O. Pantzer read a paper on "Conservative Surgery of the Sclerotic Ovary." Discussed by Drs. Dunning, Dudley, Pantzer.

F. Lawrence, Chairman of the Committee on Resolutions, in the matter of the death of W. E. B. Davis, presented the following resolutions:

Whereas, The late Dr. W. E. B. Davis was for many years an earnest, honest and fearless worker in the Section on Obstetrics and Diseases of Women of the American Medical Association, and

Whereas, His kindly manner, his forceful character and his masterful intellect have contributed much to the success of the Section both scientifically and fraternally, and

Whereas, He was one of the most efficient of our many chairmen; therefore, be it

Resolved, That in his death the Section loses one of its most valued and honored members; the profession loses one of its most worthy workers; the nation loses a man worthy a hero's laurels. Though dead his beneficent efforts and his scientific spirit will live in the hearts of his co-workers so long as human suffering demands patience, energy, sympathy and skill.

Resolved, That a copy of these resolutions be spread on the minutes of this Section and an engrossed copy be sent to his widow and children.

F. F. Lawrence, Chairman; J. H. Carstens, A. H. Cordier.

W. D. Haggard read a paper entitled "A Study of Intestinal Perforations in Typhoid Fever, with Report of Three Successful Operations and Collective Investigation of 295 Cases of Operation." Discussed by Ricketts and Thienhaus.

On motion a vote of thanks was extended to the Chairman and Secretary for efficient services.

Adjourned *sine die.*

Section on Surgery and Anatomy.

Tuesday, May 5—Afternoon.

The meeting was called to order at 2 p. m. by the Chairman, James E. Moore, Minneapolis.

The Chairman's address, entitled "A Plea for Exploratory Operations," was read.

H. J. Whitacre, Cincinnati, read a paper entitled "Suppression of Urine; Report of a Case Enduring Eight Days, Relieved by Decapsulation of the Kidneys."

J. R. Guthrie, Dubuque, Iowa, read a paper entitled "Fat Necrosis of the Kidney."

Alex. Hugh Ferguson, Chicago, read a paper entitled "The Surgical Treatment of Nephritis."

The Chairman then introduced Dr. Adolph Lorenz of Vienna, who spoke as follows: "I do not intend to impose on your kindness. As far as I know, some ten or fifteen minutes are accorded to every speaker. I will only take one or two minutes, just to thank you for your welcome and to wish a courteous success to the members of the Section."

The papers previously read were then discussed by the following: Arthur Dean Bevan, Chicago; Jepson, Iowa; McLaren, Minnesota; R. H. Gibbons, Scranton, Pa.; Ramon Guiteras, New York; McArthur, Chicago; F. A. Dunsmoor, Minneapolis; Winslow, Baltimore, and Whitacre and Ferguson.

B. B. Davis, Omaha, read a paper entitled "Indications for Cholecystectomy."

F. A. Dunsmoor, Minneapolis, read a paper entitled "The Call for Exploratory Operation in the Gall Bladder Region."

These papers were discussed by W. J. Mayo, Rochester, Minn.; J. B. Murphy, Chicago; A. J. Ochsner, Chicago; Hamilton, Columbus, Ohio; Richard H. Gibbons, Scranton, Pa., and Davis and Dunsmoor.

James B. Bullitt, Louisville, Ky., moved that the Executive Committee be appointed the Nominating Committee, which motion was duly seconded and carried, and the Secretary instructed to cast the ballot therefor.

Adjournment until 9:30 a. m., Wednesday.

Wednesday, May 6—Morning.

The meeting was called to order at 9:30 a. m. by the Chairman.

Van Buren Knott, Sioux City, Iowa, read a paper entitled "A Contribution to the Surgery of Gastric Ulcer."

H. D. Niles, Salt Lake City, read a paper entitled "Surgical Conception of Pyloric Obstruction."

A. J. Oschner, Chicago, read a paper entitled "Clinical Observations in Stomach Surgery."

These papers were discussed by A. H. Andrews, Chicago; W. J. Mayo, Rochester, Minn.; Carl Wagner, Chicago; William L. Rodman, Philadelphia; A. H. Cordier, Kansas City; Arthur Dean Bevan, Chicago; and Knott, Niles and Ochsner.

O. Beverly Campbell, St. Joseph, Mo., read a paper entitled "The Single Cuff Method of Circular Enterorrhaphy; A New Method."

James H. Dunn, Minneapolis, read a paper entitled "Intestinal Resection, with Report of Fifteen Cases, Nine with the Button and Six with the Suture."

These papers were discussed by Jonas, Omaha; Horsely, Texas; Walker, Detroit; J. B. Murphy, Chicago; Alex. Hugh Ferguson, Chicago, and Campbell.

Arthur Dean Bevan of Chicago made the following motion: "That the Delegates of the Section on Surgery call the attention of the House of Delegates to the fact that much surgical work, such as appendicitis, gastric ulcer, typhoid perforation and gallbladder surgery, is being at the present time duplicated in two Sections of this Association, and that the very important work of obstetrics is not being sufficiently emphasized. I move that it is the sense of the Section on Surgery that its interests would be best conserved if the surgical diseases of women were transferred to the Section on Surgery, leaving to the gynecologic Section obstetrics and the diseases of the genital organs of women. I move that the Delegates of the Section on Surgery bring this matter before the House of Delegates." This motion was duly seconded and carried.

Adjourned to 2:30 p. m.

Wednesday, May 6—Afternoon.

John T. Bottomley, Boston, read a paper entitled "Multiple Osteomyelitis."

Edward H. Nichols, Boston, read a paper entitled "Osteomyelitis."

These papers were discussed by DeForest Willard, Philadelphia; J. C. Stewart, Minneapolis; J. B. Murphy, Chicago; Richard Gibbons, Scranton, Pa., and Nichols.

John A. Wyeth, New York, read a paper entitled "The Treatment of Vascular Tumors by the Injection of Water at a High Temperature, with Suggestions as to Its Employment in Tubercular Adenitis, Abscess, Fistulous Tracts, etc." This paper was discussed by W. J. Mayo, Rochester, Minn.; John P. Lord, Omaha; Richard H. Gibbons, Scranton, Pa., and Wyeth.

William J. Mayo, Rochester, Minn., read a paper entitled "Further Experience with the Vertical Overlapping Method for the Radical Cure of Umbilical Hernia." This paper was discussed by A. J. Ochsner, Chicago; J. B. Murphy, Chicago; Wather, Louisville; Magee, Minnesota; Alex. Hugh Ferguson, Chicago, and W. J. Mayo.

W. T. Eckley, Chicago, read a paper entitled "Evolution of the Mammalian Straight Gut, with Special Reference to Peritoneal Changes Incident to Rotation." This paper was discussed by Willis, California, and Richard H. Gibbons, Scranton, Pa.

Fred. B. Lund, Boston, read a paper entitled "The Value of Enterostomy in Selected Cases of Peritonitis." This paper was discussed by Tinker, Baltimore; Miles F. Porter, Fort Wayne, Ind.; Thomas, Washington; James B. Bullitt, Louisville, Ky.; F. A. Dunsmoor, Minneapolis, and F. B. Lund.

F. D. Smythe, Memphis, Tenn., read a paper entitled "Cholecystectomy versus Cholecystorraphy and Cholecystostomy." No discussion.

Richard H. Gibbons, Scranton, Pa., read a paper entitled "Dangers Attendant on Attempt at Gaining the Period of Interval in Operation for Appendicitis." This paper was discussed by H. D. Niles, Salt Lake City; James B. Bullitt, Louisville, Ky.; A. J. Ochsner, Chicago; W. J. Mayo, Rochester, Minn.; J. B. Murphy, Chicago, and R. H. Gibbons.

Thursday, May 7—Morning.

The meeting was called to order at 9:30 a. m. by the Chairman.

DeForest Willard, Philadelphia, read a paper entitled "Sunshine and Fresh Air versus Roentgen and Finsen Rays in the Treatment of Tuberculosis of Bones and Joints."

J. Clark Stewart, Minneapolis, read a paper entitled "Epithelioma Under the X-Ray; a Preliminary Report of the Histologic Changes."

These papers were discussed by Henry A. Christian, Boston; Edward H. Nichols, Boston; Ridlon, Chicago; Fred. B. Lund, Boston; Browden, Clarksville; James E. Thompson, Galveston, Texas, and Willard and Stewart.

John E. Summers, Jr., Omaha, read a paper entitled "Varix of the Inferior Mesenteric Vein Complicated by Chronic Ulcerative Colitis; Operation." This paper was discussed by F. D. Smythe, Memphis; Milliken, Texas, and Summers.

Charles A. Powers, Denver, read a paper entitled "Congenital Dislocation of the Radius." This paper was discussed by John T.

Bottomley; Fred. B. Lund, Boston; DeForest Willard, Philadelphia, and Powers.

John P. Lord, Omaha, read a paper entitled "Acute Epiphysitis of the Head of the Femur, Causing a Condition Subsequently Simulating C[illegible]." This paper was discussed by Ridlon, [illegible], New York, and Lord.

Adjourned until 2 p. m.

Thursday, May 7—Afternoon.

The meeting was called to order at 2 p. m. by the Chairman.

The *Nominating Committee* reported the following nominations: Chairman, Charles A. Powers, Denver; secretary, E. Wyllys Andrews, Chicago; delegate, William J. Mayo, Rochester, Minn.

On motion, duly made, seconded and carried, the Secretary was instructed to cast the ballot for these candidates, and they were unanimously elected.

W. H. Earles, Milwaukee, read a paper entitled "Necessity for More Care in the Treatment of Skull Fractures." This paper was discussed by Sherrill, Louisville, Ky.; Carl Wagner and Sullivan, Chicago; B. B. Davis, Omaha; Brown, Alabama; Lemmon, Milwaukee; Witherspoon, Illinois, and Earles.

James B. Bullitt, Louisville, Ky., read a paper entitled "Epispadias; Report of a Case Treated by a Modification of Cantwell's Method." This paper was discussed by Poorham, Martin and Fenner, New Orleans, and Bullitt.

Charles A. Powers, the chairman-elect, was then introduced by the Chairman and made the following *remarks:*

Mr. Chairman and Gentlemen: To be elected the presiding officer over this large body of American surgeons is to me a great honor. To be the successor, as Chairman of this Section, of Murphy, Rodman, Ochsner, Walker, Mayo, Moore and DeForest Willard is to me very much of a compliment. However unworthy I am, however undeserving of this tribute I may be, I promise to serve you faithfully and to the very best of my ability.

Rudolph Matas, New Orleans, read a paper entitled "Cicatricial Ankylosis of the Jaws; a Contribution to Its Operative Treatment." This paper was discussed by J. B. Murphy, Chicago; Eastman, Indiana; Martin, New Orleans; A. J. Ochsner, Chicago, and R. Matas.

Arthur Dean Bevan, Chicago, read a paper entitled "Further Contribution to the Surgery of Undescended Testicle." This paper was discussed by W. T. Eckley and Carl Wagner, Chicago; Bartlett, St. Louis; A. J. Ochsner, Chicago; Rodman, Philadelphia, and Bevan.

J. B. Murphy, Chicago, read a paper entitled "Surgery of the Urinary Tract in the Female, Experimental and Clinical." This paper was discussed by McLaren, St. Paul; Goodhue, Ohio; Hart, Chicago; Taggert, Chicago; F. D. Smythe, Memphis; M. B. Tinker, Baltimore, and Murphy.

A. H. Levings, Milwaukee, read a paper entitled "Consideration of Mammary Cysts in the Early Diagnosis of Breast Tumors." This paper was discussed by B. B. Davis, Omaha; Sullivan, Chicago; Knight, Hartford, Conn.; Morton, California, and Levings.

Adjourned until Friday at 9 a. m.

Friday, May 8—Morning.

The meeting was called to order at 9 a. m.

Dr. Sexton read a paper entitled "Treatment of Fractures of the Femur in Plaster-of-Paris Casts." This paper was discussed by John P. Lord, Omaha; Grant, Denver; Brandon, Tennessee; Andrews, Mankato; Maurey, New York; Crouse and Sexton.

Miles F. Porter, Fort Wayne, Ind., read a paper entitled "The Closure of Wounds." This paper was discussed by John E. Summers, Jr., Omaha; Pearce, Kansas City; Morton, California; Perkins, New Orleans, and Porter.

T. C. Witherspoon, St. Louis, read a paper entitled "Operative Treatment of Exophthalmic Goiter." This paper was discussed by Grant, Denver; Rixford, California; Horsely, Texas, and Witherspoon.

F. G. Connell, Leadville, Colo., read a paper entitled "Subcutaneous Injections of Paraffin for Deformities of the Nose." This paper was discussed by Morton, California, and John P. Lord, Omaha.

Walter M. Spear, Rockland, Me., read a paper entitled "Abscess of the Spleen." No discussion.

E. J. Mellish, El Paso, Texas, read a paper entitled "Anesthesia." This paper was discussed by James E. Moore, Minneapolis; A. J. Ochsner, Chicago; M. B. Tinker, Baltimore; William J. Mayo, Rochester, Minn.; John E. Summers, Jr.; Omaha, and Mellish.

On motion of John P. Lord, Omaha, duly seconded and carried, the following papers were read by title: "Indications and Technic of Nephrectomy," Ramon Guiteras, New York; "Contributions to the Therapy of Surgical and Other Diseases with X-Rays," Rudolph Matas, New Orleans; "The Surgical Treatment of Ascites Due to Cirrhosis of the Liver," M. L. Harris, Chicago.

A. J. Ochsner, Chicago, moved that this Section extend its most hearty thanks to Dr. Moore, our President, and Dr. Monroe, our Secretary, for having arranged one of the finest programs that has ever been before any surgical section and for having carried out the conduct of this meeting in a most masterly and successful way. This motion was unanimously carried.

Adjournment.

Section on Hygiene and Sanitary Science.

Tuesday, May 5—Afternoon.

The Chairman, H. M. Bracken, Minneapolis, called the meeting to order at 2 p. m.

Cressy L. Wilbur, Lansing, Mich., read a paper on "Co-operation: Methods of Improving the Usefulness of Statistical Classification of Causes of Death." The paper was discussed by Wilbur; J. S. Fulton, Baltimore; G. T. Swarts, Providence, R. I.

In connection with this subject-matter, Dr. Wilbur introduced resolutions, which he requested to be recommended to the House of Delegates for adoption, calling on the various state medical societies to take steps looking to the adoption of registration laws in states where none presently exist; calling on physicians throughout the United States generally to promote the securing of accurate mortality statistics by giving correct and definite statements of all causes of deaths occurring in their practice. Further, that the American Medical Association appoint a Committee on Vital Statistics, to deal with the question of proper compilation of mortality statistics, and the extension of the registration area, etc. On motion, the resolutions in question were referred to the House of Delegates for action, with the recommendation that they be adopted.

The Secretary then read the paper of W. A. King, Washington, D. C., on "Relation of Physicians to Correct Registration of Vital Statistics." The pape [illegible], Seneca Egbert, Philadelphia; T. A. Williams, [illegible]; *Cressy L. Wilbur*, Lansing, Mich.; J. N. Hur[illegible]; J. S. Fulton, Baltimore.

The Secretary then stated to the members that a smoker would be held to-night, to which they were invited, at the Old Absinthe House, Bienville and Bourbon streets.

The Chair named a Nominating Committee as follows: J. N. Hurty, Chairman; W. C. Chapman and Cressy L. Wilbur.

Wednesday, May 6—Morning.

The meeting was called to order at 9 o'clock.

The Chairman of the Committee on Nominations requested further time in which to report, as he desired to have another conference with his fellow members.

The paper, "Drainage, Sewerage and Water Supply of New Orleans," was read by George G. Earl, New Orleans, and discussed by G. T. Swarts, Providence, R. I.; J. S. Fulton, Baltimore, Md.; Seneca Egbert, *Philadelphia, and Mr. Earl.*

"Present Status of the Filtration of Water" was read by George W. Fuller of New York, and discussed by Swarts; W. C. Chapman, Toledo; E. B. Borland, Pittsburg; Seneca Egbert, Philadelphia; F. J. Mayer, Lafayette, La.; W. G. Owens, Whitecastle, La., and Mr. Fuller.

On motion, duly seconded, the thanks of the Association were extended to Messrs. Earl and Fuller for the preparation and submission of their papers.

Secretary Swarts stated that Isadore Dyer, New Orleans, had extended an invitation to the members of the Section to participate in a boat ride on Saturday, May 9, to the Lepers' Settlement in Iberville parish.

The next business in order being the appointment of an Executive Committee, to act with the Chairman, Dr. Bracken named J. S. Fulton and Seneca Egbert as such members.

F. J. Mayer offered a resolution requesting the House of Delegates to have represented on their next annual program the subject "Medical Jurisprudence." Carried. Thereon, after a lantern slide exhibition by Mr. Earl, the meeting adjourned.

Wednesday, May 6—Afternoon.

The meeting was called to order at 2:30 p. m.

The Chairman of the Nominating Committee, on behalf of his Committee, offered the following nominations: For Chairman, G. T. Swarts, Providence, R. I.; Secretary, J. S. Fulton, Baltimore, Md.; member Executive Committee, Seneca Egbert, Philadelphia; delegate to House of Delegates, H. M. Bracken, Minneapolis. On motion of Dr. Hurty, the vote of the Section was cast as a unit for the election of the officers named.

"Tent Life in the Treatment of Pulmonary Tuberculosis" was read by Dr. R. W. Craig, Phœnix, Ariz. The discussion was by J. F. McConnell, Las Cruces, N. M.; J. N. Hurty, Indianapolis; Jos. L. Watt, New York City, and G. T. Swarts.

The next paper, "Where, Under Our Form of Government, Do Public Health Powers Reside, and How Should They be Exercised?" by W. H. Saunders, Montgomery, Ala., was discussed by H. A. Moody, Mobile, Ala.; R. B. Murray, of the Marine-Hospital Service; H. D. Holton, Brattleboro, Vt.; W. H. Saunders, and, by special courtesy of the Section, J. M. Lindsay, Havana.

H. A. Moody, Mobile, Ala., then read a paper on "The Future of Preventive Medicine."

F. J. Mayer asked permission to read, in connection with Dr. Moody's paper, a paper written by himself on the same subject. It was decided, however, that the paper of Dr. Dyer should be first taken up, and that subsequently that of Dr. Mayer could be read, to be discussed in conjunction with the offering of Dr. Moody.

[illegible] New Orleans, then read a paper on "Leprosy from a [illegible]; and which was thereafter discussed by Sw[illegible], [illegible], [illegible] *French of Hawaii, and Dyer.*

By unanimous consent, the volunteer paper of Dr. Mayer was then read by the author. In connection therewith, Dr. Mayer moved the adoption of a resolution endorsing the principle of public education in the matter of hygiene, and the cause, nature and effect of contagious diseases, advocating the establishment of a school to that end, and the appointment of a committee of five to carry out the idea.

Dr. Holton moved that the resolution in question be referred to the House of Delegates, together with the papers read by Drs. Moody and Mayer on the subject.

Geo. M. Kober, Washington, D. C., suggested, as a substitute, that the two papers named be referred to the Committee on Public Health of the Association, and the House of Delegates requested to endorse the idea conveyed in the resolution, which last motion prevailed by a unanimous vote.

Messrs. George W. Fuller, New York, and George G. Earl, New Orleans, were then elected associate members of the Section.

Thereon, the Section adjourned, to meet in joint session with the Section on Practice of Medicine, in the Washington Artillery Hall, Thursday, May 7.

Section on Ophthalmology.

Tuesday, May 5—Afternoon.

The meeting was called to order by the Chairman, John E. Weeks, New York, at 2:15.

Two members of the Executive Committee being absent, the Chair appointed two gentlemen to serve in their stead during the session. Frank Allport being the member present and George E. de Schweinitz and Harold Gifford the appointed members.

On motion of Edward Jackson, the Section voted that the Executive Committee act as Nominating Committee, as had been done in former years.

Address of the Chairman, John E. Weeks, New York.

The Chair called attention to some of the rules governing the reading of papers and discussions, as follows: All papers must be read in whole or part, unless, the author being present and prepared to read the paper, the Section shall unanimously vote to have it read by title, or unless the author, being present, is prevented from reading his paper because of some disability, when the paper may be read for him. The reading of a paper shall not occupy more than twenty minutes. The member opening the discussion of a paper not to have more than ten minutes and subsequent speakers five. No member shall speak twice on the same subject.

The Chair announced an invitation by Drs. Bruns and de Roaldes to visit the Eye, Ear, Nose and Throat Hospital; hours 9 to 10 a. m.; operating day, Thursday.

The Chair also announced that the Section was invited to attend a reception by Dr. and Mrs. Bruns on Wednesday, 5 to 7 p. m., the invitation including ladies accompanying members.

The question was asked if, under the ruling, the author of a paper would be allowed to close the discussion of his subject, to which the Chair replied that he would.

The Chair requested that members, on rising to discuss a paper, announce their names and places of residence, in order that it might be known at all times who was addressing the Section.

William Campbell Posey, Philadelphia, read a paper on "Vernal Conjunctivitis," which was discussed by John E. Weeks, New York; Henry Dickson Bruns, New Orleans; Henry Gradle, Chicago; Zentmayer, Philadelphia; A. R. Baker, Cleveland; Hiram Woods, Baltimore; Stevenson, Akron, Ohio; Strickler, Cincinnati; Gifford, Omaha; Claiborne, New York; Randolph, Baltimore; Morrow, Canton, Ohio.

Rufin A. Wright, Mobile, Ala., read a paper on "Subtropical Trachoma, with Special Reference to a New Therapeutic Agent," which was discussed by James W. Dunn, Cairo, Ill.; Pfingst, Louisville; Gifford, Omaha; Bulson, Fort Wayne; Harlan, Baltimore, and Ledbetter, Birmingham, Ala.

E. C. Ellett, Memphis, Tenn., read a paper on "Experimental Study on Some Methods of Combating Post-Operative Infection of the Anterior Segment of the Globe." Discussed by E. A. Shumway, Philadelphia; Frank Allport, Chicago; de Schweinitz, Philadelphia; Claiborne, New York, and Hale, Chicago.

Louis Stricker, Cincinnati, read a paper on "Ocular Complications of Bright's Disease."

George F. Suker, Chicago, read a paper on "Albuminuric Retinitis and the Decapsulation of the Kidney."

These were discussed jointly by H. D. Bruns, New Orleans; Greenwood, Boston; Connor, Detroit; Jackson, Denver; de Schweinitz, Philadelphia; Griffin, Ann Arbor.

Wednesday, May 6—Morning.

The meeting was called to order at 9:15 a. m. by the Chairman.

George E. de Schweinitz, Philadelphia, read a paper on "The Physiology of the Sympathetic in Relation to the Eye."

William H. Wilder, Chicago, read a paper on "The Influence of Resection of the Superior Ganglion of the Cervical Sympathetic in Glaucoma."

James Moore Ball, St. Louis, read a paper on "Influence of Resection of the Cervical Sympathetic in Optic Nerve Atrophy, Hydrophthalmos and Exophthalmic Goiter."

John E. Weeks, New York, read a paper on "Pathology of the Cervical Sympathetic."

Discussion on Symposium by G. Melville Black, Denver; G. C. Savage, Nashville, Tenn; George F. Suker, Chicago; Edward Jackson, Denver; George E. de Schweinitz, Philadelphia.

Henry Gradle, Chicago, read a paper on "Retinal Disease Limited to the Region of the Macula Lutea." Discussed by W. L. Dayton, Lincoln, Neb.; Leartus Connor, Detroit; C. W. Hawley, Chicago.

Casey A. Wood, Chicago, chairman of the Committee on the Pathologic Exhibit, delivered an address on "Methods of Preparing and Preserving Ophthalmic Specimens for the Museum."

Edward Jackson, Denver, read a paper on "Skiascopy as a Method of Precision." Discussed by O. A. Griffin, Ann Arbor; Harold Gifford, Omaha; William H. Wilder, Chicago; C. W. Hawley, Chicago.

Wednesday, May 6—Afternoon.

The meeting was called to order at 2:10 p. m. by the Chairman.

"Some Points in the Pathology of Neoplasms of the Conjunctiva, Illustrated by the Present Exhibit of Morbid Growths." Edward A. Shumway, Philadelphia.

Casey A. Wood, Chicago, gave a stereopticon exhibit of the fundi of various lower animals. Subject, "A Stereopticon Demonstration of Dr. Lindsay Johnson's Method of Classifying the Mammalia by the Appearances of the Fundus Oculi."

Robert L. Randolph, Baltimore, chairman of the Committee on Bacteriologic Exhibit, delivered an address on "The Bacteria Concerned in the Production of Eye Inflammations," and exhibited a number of illustrative lantern pictures.

"Bacteria in the Conjunctiva, Cornea, Iris, Ciliary Body and Chorioid, and Changes Caused Thereby," was illustrated with stereopticon slides by Brown Pusey, Chicago.

"The Essentials and Unessentials of Ophthalmic Asepsis." Harold Gifford, Omaha. Discussed by Casey A. Wood, Chicago; I. J. Dunn, Erie; W. H. Dudley, Easton, Pa.; A. O. Pfingst, Louisville; A. R. Baker, Cleveland; E. C. Ellett, Memphis; W. R. Parker, Detroit; J. H. Claiborne, New York, and Harold Gifford, Omaha.

"Development of the Fusion Center in the Treatment of Strabismus." Nelson M. Black, Milwaukee, Wis.

"A Set of Charts for Stereoscope to Be Used for an Ambylopic Eye or for Treatment of Squint." Albert B. Hale, Chicago.

Discussion on these two papers by G. C. Savage, Nashville, Tenn.; Casey A. Wood, Chicago; Edw. Jackson, Denver; M. D. Stevenson, Akron, Ohio.

The Secretary read a communication pertaining to a united meeting of various ophthalmologic and otologic societies, from the Secretary of the Academy of Ophthalmology and Oto-Laryngology, which was referred to the Executive Committee.

"Cramp of the Ciliary Muscle Due to Eyestrain." J. W. Wright, Columbus, Ohio. Discussed by Edw. Jackson, Denver; John A. Donovan, Butte, Mont.; Lawrence R. Ryan, Galesburg, Ill.

Thursday, May 7—Morning.

The meeting was called to order at 9:15 a. m. by the Chairman.

"Some Observations on the Eye Complications of Smallpox During the Recent Epidemic in Cleveland." A. R. Baker, Cleveland, Ohio. Discussed by J. F. Fulton, St. Paul; Leartus Connor, Detroit; Mann, Texarkana; Jno. A. Donovan, Butte, Mont.; R. W. Miller, Los Angeles; Oscar Dodd, Chicago; E. P. Morrow, Canton, Ohio; D. A. Thompson, Indianapolis; Greenwood, Boston; F. W. Hilscher, Spokane; Jno. E. Weeks, New York.

"Skin Grafting on the Eyelids." Oscar Dodd, Chicago.

"Entropion and the Operations Employed for Its Relief." Jno. O. McReynolds, Dallas, Tex. Dr. McReynolds requested from the Chair the privilege of making a few remarks as an addendum to his paper of last year on the pterygium operation, which was granted.

The above two papers were discussed by Albert B. Hale, Chicago; Wm. H. Wilder, Chicago; C. W. Hawley, Chicago; Frank C. Todd, Minneapolis; R. W. Miller, Los Angeles; Oscar Dodd, Chicago.

"Traumatic Lesions of the Ocular Adnexa, with Report of a Case of Contused Wound of the Eyebrow Resulting in Complete Monocular Blindness Unaccompanied by Ophthalmoscopic Changes." Eliet O. Sisson, Keokuk, Iowa. *Discussed by* Casey A. Wood, Chicago; Wm. Campbell Posey, Philadelphia; Harold Gifford, Chicago; Jno. O. McReynolds, Dallas; Oscar Dodd, Chicago; Greenwood, Los Angeles; Edw. Jackson, Denver; A. E. Bulson, Ft. Wayne, Ind.; Leartus Connor, Detroit; Zentmayer, Philadelphia; S. L. Ledbetter, Birmingham, Ala.; John E. Weeks, New York.

"Report of a Case of Complete Absence of Both Eyeballs at Birth." Lawrence R. Ryan, Galesburg, Ill. *Discussed by* Casey A. Wood, Chicago; James Moores Ball, St. Louis; J. H. Claiborne, Jr., New York; S. C. Ayers, Cincinnati.

EXHIBITION OF INSTRUMENTS.

Wm. C. Posey, Philadelphia, exhibited an apparatus for convenience in carrying bottles of collyria.

W. F. Suker, Chicago, exhibited an instrument to be used in connection with the Geneva ophthalmoscope, to facilitate the demonstration of the eye fundus to students.

Frank C. Todd, Minneapolis, exhibited a tendon tucker, which was an improvement on the one presented by himself last year.

Frank Allport, Chicago, introduced a resolution that

Whereas, *The eyesight and hearing of school children is of inestimable value to them for the acquiring of an education; therefore, be it*

Resolved, That it is advised by the American Medical Association that measures be taken by the various school authorities and boards of education, boards of health, and if possible state legislators, to secure examinations of the eyes and ears of all school children in this country with a view to the suitable treatment for the relief of the ophthalmologic and otologic imperfections.

On motions of G. C. Savage, Nashville, Tenn., and amended by Edw. Jackson, Denver, these resolutions were endorsed by the Section and recommended to the House of Delegates of the American Medical Association.

Thursday, May 7—Afternoon.

The meeting was called to order by the Chairman at 2:15 p. m.

The report of the Nominating Committee was: Chairman, R. L. Randolph, Baltimore; secretary, A. E. Bulson, Ft. Wayne, Ind.; delegate, Casey A. Wood, Chicago. A motion by Dr. Savage to adopt the report in full was carried. The Section voted that the Secretary cast the ballot for the nominees and they were declared elected.

Dr. de Schweinitz, for the Executive Committee, recommended to the Section the adoption of the following rule: Any member of the Section on Ophthalmology of the Association who has twice permitted his name to be listed on the program of the Section as intending to read a paper and has failed to attend the sessions at which these papers were due, and to give satisfactory explanation of his absence, shall be no longer eligible to read a paper before this Section until he has attended at least two consecutive sessions. On motion of Dr. Baker the recommendation was adopted as a rule of the Section.

On motion of Dr. Moulton a vote of thanks was extended the gentlemen who had so kindly allowed the use of the stereopticon. On motion of the Secretary the Section gave a vote of thanks to Dr. Bruns for his assistance and to Dr. and Mrs. Bruns for their courtesy and hospitality to the Section.

"Extraction of the Crystalline Lens in High Myopia." H. V. Würdemann and Nelson M. Black, Milwaukee.

"The Management of High Myopia." J. H. Claiborne, New York.

These two papers were discussed by Edw. Jackson, Denver; Albert B. Hale, Chicago; H. D. Bruns, New Orleans; G. M. Black, Denver; J. F. Fulton, St. Paul; Moulton, Ft. Smith, Ark.; Oscar Dodd, Chicago; de Schweinitz, Philadelphia; Leartus Connor, Detroit; Greenwood, New Orleans; Jno. E. Weeks, New York.

"Calcareous Degeneration of Corneal Cicatrices." H. Moulton, Ft. Smith, Ark.

"The Voluntary and Involuntary Brain Centers Controlling the Ocular Muscles." G. C. Savage, Nashville, Tenn. Discussed by Edw. Jackson, Denver.

Under the head of miscellaneous business the Chairman explained the reasons why Prof. Uhthoff failed to be present as a guest of the Section.

On motion of the Secretary a vote of thanks was extended to the Pathologic Committee who prepared the exhibit.

On motion of the Secretary a vote of thanks was extended to the Committe who prepared the Bacteriologic Exhibit.

Leartus Connor, Detroit, offered a resolution, that a committee of five, consisting of the last five ex-chairmen of this Section, be requested to make a study of the situation of the relation of this Section to the ophthalmologists of the United States, to the end that they may determine in what way a larger number can be brought into co-operation with this Section. An amendment was offered by Dr. Savage, that Dr. Connor be included in the committee. The amended motion was adopted.

At the suggestion of Dr. Edw. Jackson, Denver, the Section gave a vote of thanks to the officers of this Section.

Section on Diseases of Children.

Tuesday, May 5—Afternoon.

Called to order at 2:35 p. m. Attendance 100.

The Chairman, John C. Cook, Chicago, delivered his address on "Development and Care of Children," and presented to the members the bibliography of the same in printed form.

In the absence of two members of the Executive Committee the Chairman appointed to act *pro tem.*: Drs. A. C. Cotton, Chicago, and H. E. Tuley, Louisville, Ky.

It was moved and carried that a suggestion of the Chairman in his address that each state should have a committee of five persons to have control of matters of education and child labor and that these should be appointed by judges of the Supreme Court, so as to remove these matters forever from the domain of petty politics, be referred to the House of Delegates for action.

The Secretary read Sections 6 and 7 of the By-laws.

Paper 2. "Anatomic and Physiologic Correspondences of Child and Adult." Wm. T. Eckley, Chicago.

Paper 3. "Is the Study of Pediatrics Worth the Attention It Gets, and Does It Get the Attention It Deserves?" C. F. Wahrer, Fort Madison, Iowa. Discussed by W. F. Boggess, Louisville, Ky.

Paper 5. "Acute Suppurative Cervical Adenitis of Infancy. Thomas S. Southworth, New York. Discussed by A. C. Cotton, Chicago; C. G. Kerley, New York; R. B. Gilbert, Louisville; Brown, Decatur, Ill.; E. T. Shelly, Atchison, Kan.; Wm. T. Eckley, Chicago; Wm. C. Williams, Chicago; J. C. Mastin, Chicago; H. A. Leavell, Louisville, Ky., and T. S. Southworth.

H. M. McClanahan moved that, in view of the death of Dr. Margaret Taylor Shutt of Springfield, Ill., since the last annual session, a committee be appointed by the Chairman to draw up suitable resolutions and transmit them to her family. Carried.

The Section then adjourned.

Wednesday, May 6—Morning.

Called to order at 9:09 a. m. Attendance 175.

Paper 6. "The Pathology of Summer Diarrheas of Children," by G. W. Boot, Evanston, Ill., was, in Dr. Boot's absence, read by the Secretary.

On motion of Dr. C. G. Kerley of New York the discussion on the symposium was postponed until the other papers had been read.

Paper 7. "Every-Day Problems in Infant Feeding." Henry Enos Tuley, Louisville, Ky.

Paper 8. "Infant Feeding." Alexander McAlister, Camden, N. J.

Paper 9. "The Infant Digestive Disturbances." Alfred C. Cotton, Chicago.

Paper 10. "Suggestions for Reducing the Prevalency of Summer Diarrhea." J. Ross Snyder, Birmingham, Ala.

Paper 11. "Observations on Breast Feeding from an Obstetrician's Point of View, with Report of Cases." Effa V. Davis, Chicago.

Paper 12. "Aphthæ and Herpes Contracted by Children Drinking Milk from Cows Suffering from Foot and Mouth Diseases." E. F. Brush, Mt. Vernon, N. Y.

Paper 15. "Observations on Prolonged Withdrawal of all Foods in the Management of Certain Cases of Intestinal Disorders." Thomas D. Parke, Birmingham, Ala.

Discussion on symposium (Papers 6 to 15) by H. M. McClanahan, Omaha; C. G. Kerley, New York; R. B. Gilbert, Louisville, Ky.; Dixon, Kentucky; Auld, Chicago; Parkhurst, Indiana; T. S. Southworth, New York.

The discussion was then voted to be continued at the afternoon meeting.

The Section adjourned.

Wednesday, May 6—Afternoon.

Called to order at 2:40 p. m. Attendance 100.

Paper 14. "Infant Feeding: Its Relation to Diarrheal Diseases of Infancy." James G. Mastin, Chicago.

Discussion continued on symposium by George N. Acker, Washington, D. C.; Southworth, New York (for Dr. G. W. Boot); Henry E. Tuley, Louisville, Ky.; A. C. Cotton, Chicago; J. Ross Snyder, Birmingham, Ala.; Effa V. Davis, Chicago; James G. Mastin, Chicago; Thomas D. Parke, Birmingham, Ala.

H. E. Tuley, Louisville, then moved that a committee be appointed by the Chairman to draw up a classification of the intestinal diseases of children, to be submitted to the Section in 1904. Carried.

Paper 18. "Case of Probable Gummata of the Liver in a Child of Six." Maurice Ostheimer, Philadelphia. Discussion by R. B. Gilbert, Louisville, Ky., and C. F. Wahrer, Fort Madison, Iowa.

Paper 34. "Influenza in Children." Wm. Carver Williams, Chicago. Discussion by R. B. Gilbert, Louisville, Ky.; C. G. Kerley, New York; Parkhurst, Indiana; H. M. McClanahan, Omaha; Theo. J. Carlin, Minnesota; John C. Cook, Chicago; C. F. Wahrer, Fort Madison, Iowa; J. H. Hanna, Covington, Tenn., and Wm. Carver Williams, Chicago.

The Section adjourned.

Thursday, May 7—Morning.

Called to order at 9:15 a. m. Attendance 125.

Chairman announced as committee to submit a classification of the intestinal diseases of childhood to Section in 1904: Henry Enos Tuley, Louisville, Ky.; Alfred C. Cotton, Chicago; Thomas S. Southworth, New York.

Paper 19. "Capillary Bronchitis." Philip F. Barbour, Louisville, Ky.

On motion of Dr. Kerley, discussion on the pulmonary papers was postponed until the others had been read.

Paper 21. "Management of Catarrhal Pneumonia in Infants and Young Children." Charles Gilmore Kerley, New York.

Discussion on Papers 19 and 21 by C. F. Wahrer, Fort Madison, Iowa; Wm. C. Williams, Chicago; R. B. Gilbert and H. E. Tuley, Louisville, Ky.; Thos. D. Parke, Birmingham, Ala.; H. A. Leavell and P. F. Barbour, Louisville, Ky.; C. G. Kerley, New York.

Paper 31. "The Safranin Reaction in the Urine of Children," by Dr. W. S. Christopher of Chicago, was read by Dr. A. C. Croftan, Chicago. Discussion by A. C. Croftan, Chicago, and W. F. Boggess, Louisville.

P. F. Barbour, Louisville, moved that the unanimous thanks the Section be tendered to the Chairman for the complete bibli raphy of his paper which he had presented in printed form the members. Carried.

The Section then adjourned.

Thursday, May 7—Afternoon.

Called to order at 2:40 p. m. Attendance 100.

The Nominating Committee put in nomination for 1904: Ch man, Charles G. Kerley, New York; Secretary, C. F. Wahrer, F Madison, Iowa. These were unanimously elected.

J. R. Snyder nominated Henry E. Tuley, Louisville, as the D gate of the Section, in the House of Delegates for two years, a the Secretary was empowered to cast one ballot for Dr. Tuley.

The Chairman then presented to Dr. Kerley a gavel to be us in Section work, to which Dr. Kerley fittingly replied.

Paper 26. "The Treatment of Scarlet Fever: Its Complicati and Sequelæ." H. M. McClanahan, Omaha. Discussion by R. Gilbert, Louisville, Ky.; G. A. Hermann, Hamilton, Ohio; J. Hanna, Covington, Tenn.; B. R. Shurly, Detroit; E. T. Shel Atchison, Kan.; Dodson, Chicago; Pearson, Kansas; Kenne Kentucky, and H. M. McClanahan.

Paper 30. "Prolonged or Retained Intubation Tubes with Method of Treatment Leading to Their Extraction." B. R. Shur Detroit. Discussion by C. G. Kerley, New York, and Brow Illinois.

Paper 28. "Hydronephrosis in a Boy of Three and One-h Years, with Operation and Recovery," by Samuel W. Kelley, Cle land, Ohio, was then read by the Secretary.

The Section, having completed its work, then adjourned to t next annual session.

Section on Stomatology.

Tuesday, May 5—Afternoon.

The Section was called to order by the Chairman, M. L. Rhe of New York.

It was moved that the papers presented by those unavoidably a sent should be read. Carried.

W. E. Walker, New Orleans, and M. H. Fletcher, Cincinnati, we appointed on the Executive Committee

The address of the Chairman, M. L. Rhein, was read and w discussed by Frederichs, Eames, Boston; Gilmer, Chicago; T. Constant, Scarborough, Eng.; W. E. Walker, C. V. Vignes, Ne Orleans; Talbot, Chicago, and Rhein.

Drs. Eames, Walker and Talbot were appointed a committee t consider the subject of the Chairman's address and to form resol tions thereon.

It was resolved that the following gentlemen of other countrie be elected members of this Section of the American Medical Ass ciation by invitation: A. C. Spaulding, Paris; T. E. Constant Scarborough, Eng.; D. E. Causch, Brighton, Eng.; Michael Mor ganstein, Strassburg, Germany; Oskär Römer, Strassburg, Ger many.

It was resolved that the following local residents be made asso ciate members of the Section on Stomatology of the America Medical Association: C. Edmund Kelk, Jr., Paul de Verges, Jule J. Sarrazin, H. E. Belden.

A paper entitled "The Vasomotor System" was read by Eugen S. Talbot and illustrated by slides. Discussed by Fletcher, Constant, Gilmer, Eames, Belden, Sarrazin and Talbot.

Exhibition of Slides in demonstration of a paper entitled "Th Development of Hard Tissue in the Pulp," by D. E. Causch o Brighton, Eng.

A paper by Martha Anderson, Moline, Ill., entitled "Notes on Pulp Technic," was read by E. S. Talbot.

Exhibition of Slides in demonstration of a paper entitled "Tolerance of Tissues for Foreign Bodies, with Special Reference to the Pulp and Peridental Membrane," by M. H. Fletcher, Cincinnati.

Exhibition of Slides in demonstration of a paper entitled "Some Histologic Facts Contradictory to the Theory of Odontoblasts," by Michael Morganstein, Strassburg, Germany.

The following were appointed a Nominating Committee: A. E Baldwin, Chicago; M. H. Fletcher, Cincinnati; W. E. Walker, New Orleans.

Wednesday, May 6—Afternoon.

The Section was called to order at 2:25 by A. E. Baldwin, Chicago, in the Chair.

M. H. Fletcher of Cincinnati read a paper entitled "Tolerance of Tissues for Foreign Bodies, with Special Reference to the Pulp and Peridental Membrane." The paper was discussed by Talbot, Baldwin, Curtis, Rhein, H. Pilcher of Vienna, Eames, Walker and Fletcher.

It was resolved that all papers on the pulp be read and discussed jointly.

A paper entitled "The Dental Pulp Viewed without the Microscope" was read by T. E. Constant, Scarborough, Eng.

A paper entitled "Some Histologic Facts Contradictory to the Theory of Odontoblasts," by Dr. Michael Morganstein, Strassburg, Germany, was read by A. E. Baldwin.

"The Development of Hard Tissue in the Pulp of Human Teeth," by D. E. Causch, Brighton, Eng., was read by G. F. Eames.

A paper on "Pulp Hypertrophy of the Teeth," by Oskär Römer, Strassburg, Germany, was read by M. L. Rhein.

These papers were discussed by Talbot and Fletcher. At this point the discussion was postponed until the next meeting.

A. E. Baldwin made the report from the House of Delegates.

Thursday, May 7—Morning.

The meeting was called to order at 10:15 by the Chairman, M. L. Rhein.

The adjourned discussion of the paper of T. E. Constant was continued by Fletcher, Pilcher, Baldwin, Walker, Eames, Rhein and Constant.

Dr. Baldwin made a supplemental report from the House of Delegates to the effect that any dentist holding the degree of D.D.S. from any reputable dental college, and being a member of his local dental and state society shall, on recommendation of the officers of the Section and vote of the Section, become a dental member of the American Medical Association; and shall enjoy all the privileges of regular members.

The Nominating Committee made the following report, and the Secretary was authorized to cast the ballot for its adoption: G. F. Eames, chairman; Eugene S. Talbot, secretary; executive committee: A. H. Peck, R. R. Andrews and M. L. Rhein. Member to the House of Delegates, Dr. A. E. Baldwin.

A. E. Baldwin read a paper on "Professional Responsibilities." Discussed by T. E. Constant of England, Gilmer, Talbot, Curtis, Rhein, Pilcher, Walker, Eames and Baldwin.

A paper by O. N. Heise, Cincinnati, entitled "Empyema of the Maxillary Sinus," was read by G. F. Eames, and discussed by Gilmer, Fletcher, Constant, Rhein, Baldwin and Curtis.

Thursday, May 7—Afternoon.

The meeting was called to order at 2:10 p. m. by M. H. Fletcher in the Chair.

G. F. Eames read a paper on "The Influence of Local and General Disturbances on the Oral Secretions." Discussed by Talbot, Fletcher, Walker, Pilcher and Eames.

A paper by Charles Chittenden, Madison, on "Is the Accomplishment of Reasonable Ideals in Dental Education Near at Hand?" was read by W. E. Walker, New Orleans, and discussed by Talbot, Fletcher, Rhein, Constant, and Walker.

W. E. Walker read a paper entitled "Orthodontic Facial Orthopedia." Discussed by Talbot, Constant, Fletcher, Belden, Rhein and Walker.

H. E. Belden, New Orleans, read a paper entitled "Methods of Controlling Hemorrhage of the Oral Cavity." Discussed by Rhein, Eames and Belden.

On motion the paper of Richard Gray, Baltimore, on "The Dentist in the U. S. Army, and of Alice M. Steves, Boston, entitled "Medical and Dental Libraries," were read by title.

G. F. Eames, Chairman of the Committee to consider the suggestions of the Chairman's Address, reported and the report was adopted, as follows:

Your committee have carefully considered the propositions contained in the Chairman's Address, relating to the training of women as dental nurses, that they may, under the prescription and personal direction of the stomatologist, cleanse and sterilize the mouth, polish the teeth, make medical applications to the gums, and otherwise assist the practitioner in his treatment of patients.

Your committee heartily approves the above named suggestions and earnestly commends the matter for the approval of this Section of the American Medical Association, hoping that it will lead to such action being taken by different state dental societies looking to the amendment of our dental laws, so that the appointment and employment of "dental nurses" shall be legalized.

Section on Nervous and Mental Diseases.

Tuesday, May 5—Afternoon.

The meeting was called to order at 2 p. m. by F. W. Langdon, Cincinnati, Chairman.

The Chairman said: It affords me great pleasure to say to you that, owing to the industry and efficiency of our worthy Secretary, we have to present to you at this meeting a most attractive and somewhat extensive program, which, providing we digest and assimilate it properly, can not fail to be of benefit to us and to mankind through us. I am also admonished that the length of the program and the limited time at our disposal requires that we waste no time in preliminaries, and I therefore pronounce the session of the Section on Nervous and Mental Diseases open. As Chairman, one of my privileges is to have the right of way, and, in order that I may not take up too much of your valuable time, I shall present a mere abstract of my address.

Sir William Gowers and Sir Victor Horsley, both of London, have been requested by me to become members of our Section by invitation. Both have accepted, but are unable to be present.

I wish to announce that the annual banquet of the Section will be held to-night at Victor's Restaurant, on Bourbon street, at 8 o'clock.

Address of Chairman. F. W. Langdon, Cincinnati.

H. T. Patrick, Chicago: I move that the thanks of the Section be extended to the Chairman for his address, and that it be referred to the Executive Committee. Carried.

"Trend of Modern Psychiatry and Its Relation to General Medicine." John Punton, Kansas City, Mo. Discussed by F. Savary Pearce, Philadelphia; Daniel Brower, Chicago; R. H. Cook, Oxford, Ohio; McBride, Pasadena, Cal.; Dewey, Wauwatosa, Wis.; A. E. Sterne, Indianapolis; W. J. Herdman, Ann Arbor, Mich.; G. W. McCaskey, Fort Wayne, Ind., and Punton.

The Chairman named the following to serve as a Nominating Committee: H. T. Patrick, John Punton and W. Sinkler.

Dr. Patrick: As there is nothing to do to-morrow morning, and we have a very extensive program, I move that we have a morning session at 10 o'clock. Carried.

"A Contribution to the Study of Visual Disturbances in Brain Injury." William E. Gamble, Chicago. Discussed by H. T. Pershing, Denver; H. T. Patrick, Chicago; McBride, Los Angeles, Cal.; W. T. Eckley, Chicago, and Gamble.

"Epilepsy; a Clinical Study." J. G. Biller, Cherokee, Iowa.

"Pathology of Inebriety." T. D. Crothers, Hartford, Conn. Discussed by Petty, Memphis, Tenn.; A. E. Sterne, Indianapolis, and Crothers.

Wednesday, May 6—Morning.

The meeting was called to order at 10 a. m.

The minutes of the last meeting were read and approved.

The Secretary read a letter from the Chairman of the Section on Ophthalmology, stating that 2 o'clock, at the College of Pharmacy, Casey Wood would give a stereopticon demonstration of Dr. Lindsay Johnson's method of classifying the mammalia by the appearance of the fundus oculi. All members of the Association were cordially invited.

"Ambulatory Automatism." Hugh T. Patrick, Chicago. Discussed by Brainard, Los Angeles; Albert E. Sterne, Indianapolis; John Punton, Kansas City; Wharton Sinkler, Philadelphia; P. E. Archinard, New Orleans; W. J. Herdman, Ann Arbor, Mich.; F. W. Langdon, Cincinnati; C. C. Hersman, Pittsburg; F. Savary Pearce, Philadelphia; D. I. Wolfstein, Cincinnati, and Patrick.

Wednesday, May 6—Afternoon.

"Penetrating Wound of Both Cerebral Hemispheres, with Recovery." W. S. Lindsay, Topeka, Kan. Discussed by H. T. Pershing, Denver; F. Savary, Pearce, Philadelphia; Brainard, Los Angeles; Albert E. Sterne, Indianapolis, and Lindsay.

The Nominating Committee recommended the following names for election: Chairman, F. Savary Pearce, Philadelphia; secretary, David I. Wolfstein, Cincinnati; member of the House of Delegates, F. W. Langdon, Cincinnati. It was moved and seconded that the report of the Nominating Committee be adopted. Carried.

"Relation of Epilepsy to Chronic Gastro-Intestinal Diseases." G. W. McCaskey, Fort Wayne, Ind.

"Neurasthenia and Its Treatment by Actinic Rays." Albert E. Sterne, Indianapolis. Discussed by F. Savary Pearce, Philadelphia; David I. Wolfstein, Cincinnati; John Punton, Kansas City; W. J. Herdman, Ann Arbor, Mich.; C. C. Hersman, Pittsburg; F. W. Langdon, Cincinnati, and A. E. Sterne.

SYMPOSIUM ON RELATION OF PUBLIC SCHOOL METHODS TO PSYCHOSES.

"Relation of the Public School to the Seminary and College as to Psychoses." F. Savary Pearce, Philadelphia.

"Best Methods of Counteracting Psychoses Due to Strain and Stress." William J. Herdman, Ann Arbor, Mich.

The two papers were discussed by Harold N. Moyer, Chicago; John Punton, Kansas City; J. H. McBride, Los Angeles; R. C. Moore, Omaha; T. A. Williams, East Bernard, Texas; A. E. Sterne, Indianapolis, and Daniel W. Brower, Chicago.

Thursday, May 7—Morning.

Called to order at 10 o'clock.

Continuation of the discussion on the relation of public school methods to psychoses, by D. O. Wilkinson, Montibello, Ala.; Wharton Sinkler, Philadelphia; D. I. Wolfstein, Cincinnati; A. J. Pressey, Cleveland; C. C. Hersman, Pittsburg; Shelley, Atchinson, Kan.; T. A. Williams, East Bernard, Texas; C. C. Hersman, Pittsburg; J. H. McBride, Pasadena, Cal.; H. T. Patrick, Chicago; W. S. Lindsay, Topeka, Kan.; F. W. Langdon, Cincinnati; Albert E. Sterne, Indianapolis; F. Savary Pearce, Philadelphia, and William J. Herdman, Ann Arbor, Mich.

William J. Herdman, Ann Arbor, Mich., presented the following resolution:

Resolved, That we, the members of the Section on Nervous and Mental Diseases of the American Medican Association, are deeply conscious of the vital importance of the methods of education and school environment on the development of youth and are of the opinion that the time has arrived for the harmonious and helpful co-operation of educators and physicians in the work of education. In view of this belief on our part, be it further

Resolved, That we appoint a committee from our membership at this meeting, whose duty it shall be:

First. To collect, during the coming year, such exact information as may be accumulated, both in this country and in Europe, on the school methods in their relation to the physical and mental welfare of youth.

Second. To confer with leading educators everywhere with the view of eliciting information and opinions on the subject and of securing co-operation in efforts for improvement of methods.

Third. To report to the Section at its next annual session the results of their investigations, and formulate a plan for future and vigorous prosecution of such reforms as we may decide from their report are clearly needed.

In accordance with the above resolution, which was adopted, the Chairman named the following committee: William J. Herdman, Ann Arbor, Mich., chairman; T. A. Williams, East Bernard, Texas; J. H. McBride, Los Angeles, Cal.; F. Savary Pearce, Philadelphia, and H. T. Patrick, Chicago.

John Punton inquired whether it would be possible to get the papers which were read before the Section on Nervous and Mental Diseases and the discussion thereon in book form, without waiting for the appearance of the transactions in The Journal of the American Medical Association.

The Chairman appointed Dr. Punton a committee of one to inquire into the matter and report at the afternoon meeting. (Report was in the negative.)

"Atrophy of Hand Muscles, with Localized Sensory Disturbances; *Possible Early Syringomyelia.*" D. I. Wolfstein, Cincinnati. Discussed by H. T. Patrick, Chicago; Wharton Sinkler, Philadelphia; A. E. Sterne, Indianapolis; F. W. Langdon, Cincinnati, and D. I. Wolfstein, Cincinnati.

Thursday, May 7—Afternoon.

F. Savary Pearce reported that the committee which had been appointed in the morning to consider the relation of public school methods to psychoses had already held one meeting, and they hoped to make considerable progress before the next annual session of the Section.

"Ten Cases of Chronic Morphinism and Results of Treatment." A. J. Pressey, Cleveland, Ohio. Discussed by George E. Petty, Memphis, Tenn., and A. J. Pressey.

"The Nervous Phenomena Associated with Movable Kidney." Wharton Sinkler, Philadelphia. Discussed by A. P. Ohlmacher, Gallipolis, Ohio; R. C. Moore, Omaha; J. L. Miller, Chicago; A. R. Elliot, Chicago; A. C. Croftan, Chicago, and F. Savary Pearce, Philadelphia.

"A Consideration of the Neuroses of the Status Lympaticus." A. P. Ohlmacher, Gallipolis, Ohio. Discussed by D. I. Wolfstein, Cincinnati; A. P. Ohlmacher; H. T. Pershing, Denver; H. T. Patrick, Chicago; D. I. Wolfstein, and A. P. Ohlmacher.

"Carcinoma of Spine and Meninges Secondary to Cancer of the Breast." F. Savary Pearce, Philadelphia. Discussed by H. T. Pershing, Denver, and F. Savary Pearce.

"Some Toxemias in Relation to the Production of Nervous and Mental Diseases." Samuel Bell, Detroit.

"Treatment of Emotional Disturbances." Howell T. Pershing, Denver. Discussed by H. T. Patrick, Chicago; John Punton, Kansas City; B. F. Turner, Memphis, Tenn.; F. Savary Pearce, Philadelphia, and H. T. Pershing.

The Chairman: I am pleased to announce that this completes the work of the Section on Nervous and Mental Diseases. We have listened to an excellent program, and have been able to complete it in three days by holding two daily sessions instead of one.

R. C. Moore, Omaha: I move that the thanks of the members of the Section be extended to the Chairman and Secretary for the admirable way in which they have conducted the proceedings. Unanimously carried.

Section on Cutaneous Medicine and Surgery.

TUESDAY, MAY 5—AFTERNOON.

The Section was called to order at 2 p. m. by the Chairman, John A. Fordyce, who gave an address on "The Modern Conception of Eczema." It was discussed by Zeisler, Illinois; Bulkley, New York; Ohmann Dumesnil, Missouri.

H. R. Varney, Detroit, read a paper on "Results in Radiotherapeutics and Clinical Conclusions." Discussed by Skinner, Connecticut; Zeisler, Illinois; Bulkley, New York; Hubbard, Tennessee; Campbell, Illinois; Edwards, Tennessee: Ohmann Dumesnil, Missouri; Duncan, Missouri; Guthrie, New York; Roussel, Louisiana; Varney, Michigan.

The paper of Louis E. Schmidt, Chicago, entitled "Clinical Results Obtained in the Use of Finsen's and Other Lights," was read by title.

M. L. Heidingsfeld, Cincinnati, read a paper entitled "Treatment of Syphilis by Injection." Discussed by Ohmann Dumesnil, Missouri; Kessler, Iowa; Anthony, Illinois: Schamberg, Pennsylvania; Zeisler, Illinois; Weiss, New York; Heidingsfeld, Ohio.

H. G. Anthony, Chicago, read a paper entitled "Fibroma Molluscum." Discussed by Heidingsfeld, Ohio; Bulkley and Fordyce, New York; Anthony, Illinois.

The next order of business being the appointment of a Nominating Committee, it was moved and carried that the Chair appoint a committee of three, to report to-morrow. The Chair appointed Baum, Illinois; Vanderhook, Minnesota; Schamberg, Pennsylvania.

The Section adjourned to 2 p. m., Wednesday.

WEDNESDAY, MAY 6—AFTERNOON.

The Nominating Committee reported for chairman, Henry G. Anthony, Chicago; secretary, R. R. Campbell, Chicago; member of House of Delegates, Jay F. Schamberg, Philadelphia; alternate, G. W. Wende, Buffalo.

Paper, "Treatment of Leprosy," by A. H. Ohmann Dumesnil, St. Louis. Discussed by J. F. Schamberg, Pennsylvania; Duncan; Vanderhook; Roussell, Louisiana; J. A. Fordyce, New York, and Ohmann Dumesnil.

Papers of William S. Gottheil, entitled "Tuberculosis Cutis Frambesioides Disseminata," and Eugene Carson Hay, Hot Springs, Ark., on "Syphilitic Fever," and Henry Stelwagon, Philadelphia, on "Larva-Migrans," were read by title.

Paper, Joseph Zeisler, Chicago, "Notes on the Treatment of Lichen Planus." Discussed by Baum, Illinois; Schamberg, Pennsylvania; Dumesnil, Missouri; Heidingsfeld, Ohio; Duncan; Shelmire, Texas, and Zeisler.

It was voted not to accept the paper of Justin de Lisle.

Paper, "Papilloma of the Sole," by Douglas W. Montgomery, was read by title.

Paper, "Some Clinical Observations on Chicken-pox," by Jay F. Schamberg, Philadelphia. Discussion by Kessler; Baum, Illinois; Dumesnil, Missouri, and Shelmire, Texas.

Paper, "Diagnosis of Cutaneous Syphilis," by Isadore Dyer, New Orleans. Discussion by Anthony, Illinois; Heidingsfeld, Ohio, and Dyer, Louisiana.

Paper, "Report of a Case of Pemphigus Chronicus," by William Frick, Kansas City. No discussion.

Paper, "Notes on an Interesting Case of Lupus Vulgaris," by R. R. Campbell, Chicago. Discussion by Zeisler, Chicago; Anthony, Chicago; Duncan and Campbell.

THURSDAY, MAY 7—MORNING.

The clinic by Isadore Dyer at Charity Hospital was well attended. A number of most interesting cases were presented, the discussions on which were most valuable as well as highly instructive.

THURSDAY, MAY 7—AFTERNOON.

Paper, "Atrophia Cutis Idiopathica," by William S. Gottheil, New York, was read by title.

Paper, "Diagnosis of Smallpox," by A. W. Brayton, Indianapolis, was read in abstract. No discussion.

Paper, "Pathology and Treatment of Smallpox," by N. D. Brayton, Indianapolis, was read by title.

Paper, "Pityriasis Rosea," by Ludwig Weiss, New York. Discussion by Anthony, Illinois; Bulkley, New York; Brayton, Indiana; Heidingsfeld, Ohio; Fordyce and Weiss, New York.

Paper, "Scarlet Fever," by William L. Baum, Chicago. Discussion by Schamberg, Pennsylvania; Brayton, Indiana; Anthony, Illinois; Weiss, New York, and Baum, Illinois.

Paper, "Influence of the Menstrual Function on Certain Skin Diseases," by L. Duncan Bulkley, New York. No discussion.

On the suggestion of the Chairman a motion was made by Dr. Anthony, Illinois, seconded by Dr. Schamberg, Pennsylvania, and carried that the action taken yesterday in regard to the paper of Dr. de Lisle be reconsidered and the paper referred to the Executive Committee.

Dr. Weiss, New York, exhibited lantern slides illustrating his paper.

Dr. Heidingsfeld, Ohio, exhibited lantern slides in preliminary investigations of cutis atrophica.

Paper, "A Case of Blastomycetic Dermatitis from Accidental Inoculation," by Newton Evans, Battle Creek, Mich. Discussion by Brayton, Indiana; Dyer, Louisiana; Heidingsfeld, Ohio; Anthony, Illinois; Fordyce, New York, and Evans, Michigan.

A vote of thanks was given Dr. Dyer and his assistants, Drs. Menage and Hopkins, for courtesies shown.

The Section then adjourned.

Section on Laryngology and Otology.

TUESDAY, MAY 5—AFTERNOON.

This Section was called to order at 2:18 p. m. The Chairman, George L. Richards, of Fall River, Mass., presided; J. F. Barnhill, Indianapolis, Secretary.

The Secretary announced the Section banquet for the evening, a clinic at the Throat Hospital between 9 and 10 a. m. Wednesday, and a buffet luncheon 12 to 2 p. m. Wednesday.

The Chairman announced that all the members of the Executive Committee were absent, and inasmuch as there impending some important matters for the consideration of this committee, the following were appointed members: O. Joachim, New Orleans; A. G. Woolen, Indianapolis, and C. M. Cobb, Boston.

The address of the Chairman was delivered by Geo. L. Richards.

"Report of Cases, Showing Instrument and Technic in the Cure of Deafmutism." Maury M. Stapler, Macon, Ga. Discussed by O. Joachim, New Orleans; B. M. Behrens, Memphis; C. M. Cobb, Boston; Cox, Rome, Ga.; R. C. Myles, New York; H. W. Loeb, St. Louis, A. W. de Roaldes, New Orleans; Snow, Syracuse, N. Y.; and Stapler.

On motion, discussions were limited to three minutes.

"Membranous Pharyngitis." John McReynolds, Dallas, Texas. Discussed by R. C. Myles, New York; B. M. Behrens, Memphis; F. W. Hilscher, Spokane; B. R. Shurly, Detroit, and McReynolds.

"Nasal Polypus; Origin and Treatment." Charles H. Baker, Bay City. Discussed by R. C. Myles, New York; H. W. Loeb, St. Louis; Miner, Detroit; C. M. Cobb, Boston; W. Scheppegrell, New Orleans; F. W. Hilscher, Spokane, and Baker.

"Diphtheria of the Nose." W. Scheppegrell, New Orleans, read by title.

On motion by Dr. Myles, seconded and unanimously passed, Dr. Scheppegrell was asked to give the Section a talk on the use of the *x*-ray.

The following Nominating Committee was appointed: Myles, New York; Loeb, St. Louis, and Pearce, Chicago.

WEDNESDAY, MAY 6—MORNING.

The Section met in the Eye, Ear, Nose and Throat Hospital at 9 a. m.

"Some Observations on the Removal of Diseased Tonsils" was read by Charles M. Robertson, Chicago, who also demonstrated his method of operating. [This was discussed later.]

The Section then repaired to the College of Pharmacy, reconvening at 10 a. m.

W. Scheppegrell, New Orleans, moved that the retiring Chairman be one of the representatives of the Section to the House of Delegates, and that he choose from the floor the other member. The motion was seconded and unanimously passed.

"The Necessity for an Early Diagnosis and Treatment in Acute Suppurative Affections of the Middle Ear." Frank D. Boyd, Fort Worth, Texas. Discussed by H. Dupuy, New Orleans; Philip Hammond, Boston; E. C. Ellett, Memphis; D. A. Kuyk, Richmond; Harmon Smith, New York; Baker, Bay City, Mich.; Woodson, Birmingham; De Vilbiss, Toledo; J. F. Barnhill, Indianapolis; George L. Richards, Fall River, Mass.; Kate Baldwin, Philadelphia; Parker, Detroit; C. M. Cobb, Boston; J. F. Hill, Memphis; W. Scheppegrell, New Orleans, and Boyd.

A patient, from whom a necrosed arytenoid cartilage had been removed, was presented by W. Scheppegrell, New Orleans.

"Report of a Case of Empyema of the Frontal Sinus." C. A. Thigpen, Montgomery, Ala. Discussed by Myles, New York; Gordon King, New Orleans; O. T. Freer, Chicago; Pfingst, Louisville; George L. Richards, Fall River, Mass.; Homer Dupuy, New Orleans; E. E. Ingals, Chicago, and Thigpen.

The discussion of Charles M. Robertson's paper was then taken up, and was participated in by Hilscher, Spokane, Wash.; Miner, Detroit; J. F. Barnhill, Indianapolis; E. Fletcher Ingals, Chicago; Myles, New York; Loeb, St. Louis; George L. Richards, Fall River, Mass., and Robertson.

WEDNESDAY, MAY 6—AFTERNOON.

Convened at 2:35 p. m.

"Paraffin Injected Subcutaneously for the Correction of Nasal and Other Deformities." Harmon Smith, New York. Discussed by O. Joachim, New Orleans; J. F. Barnhill, Indianapolis; Robert C. Myles, New York; C. M. Cobb, Boston; E. Fletcher Ingals. Chicago, and Smith.

"The Special Influence of High Altitude on the Nose and Throat." S. E. Solly, Colorado Springs. Discussed by Melville Black, Denver; Sargent F. Snow, Syracuse, and Myles.

"A General Consideration of the Diseases of the Ethmoid Bones and Cells." Robert C. Myles, New York. Discussed by E. Fletcher Ingals, Chicago; Sargent F. Snow, Syracuse, and Solly.

"Non-Tubercular Hemorrhages of the Air Passages." L. F. Page, Indianapolis. No discussion.

"The Resection Operation for the Correction of Deflections of the Nasal Septum." Otto T. Freer, Chicago. Discussed by O. Joachim, New Orleans; J. F. Barnhill, Indianapolis; Schambaugh, Chicago; B. R. Shurly, Detroit; Gradle, Chicago; Hill, Memphis, and Freer.

R. C. Myles, New York, on behalf of the Nominating Committee, reported the following nominations: Chairman, J. F. Barnhill, Indianapolis; secretary, Otto T. Freer, Chicago; member of House of Delegates, George L. Richards, Fall River, Mass. These were elected.

THURSDAY, MAY 7—MORNING.

The Section convened at 9:30 a. m.

The following communication was read by the Secretary:

CINCINNATI, OHIO, April 27, 1903.

To the Secretary of the Section on Laryngology and Otology, American Medical Association:

Enclosed please find a resolution which was acted on by the Academy of Ophthalmology and Oto-Laryngology (formerly the Western Ophthalmologic and Oto-Laryngologic Association) at its regular annual meeting, which was held in Indianapolis, April 9 to 11.

Will you kindly read this resolution before your society at its next meeting, and if the sentiment [illegible] the approbation of your members, will you [illegible] endorsing the ideas inculcated is voted on by [illegible]

Will you kindly notify me after the regular meeting of your society what action was taken in reference to the matter?

I enclose the names of six societies which have been invited to join this federation. Any suggestions which your organization might make in reference to enlarging the idea expressed, etc., will be gratefully received.

DERRICK T. VAIL, Secretary.

THE ACADEMY OF OPHTHALMOLOGY AND OTO-LARYNGOLOGY.

At the annual meeting of the Academy of Ophthalmology and Oto-Laryngology (formerly known as the Western Ophthalmologic and Oto-Laryngologic Association), held in Indianapolis, April 9, 10 and 11, 1903, the following resolution was proposed by the president, Dr. William L. Ballenger, and seconded by the secretary, Dr. Derrick T. Vail, and adopted by the academy:

Resolved, That the Academy of Ophthalmology and Oto-Laryngology deem it wise to correspond with all other American associations devoted to the consideration of diseases of the eye, ear, nose and throat, with a view of establishing a federation of the said societies. The said federation to meet in joint session once every five years for the consideration of scientific and other subjects pertaining to the eye, ear, nose and throat.

It is suggested that the first meeting of the proposed federation be held at a time and place to be agreed on in the year 1906, or at such other time as may be selected.

WILLIAM L. BALLENGER, President.
DERRICK T. VAIL, Secretary.

Societies invited to joint the federation: American Laryngological Association; American Laryngological, Rhinological and Otological Society; American Otological Society; Section on Laryngology and Otology, American Medical Association; Section on Ophthalmology, American Medical Association; American Ophthalmological Society; Academy of Ophthalmology and Oto-Laryngology.

W. Scheppegrell, New Orleans, Chairman *pro tem*, said: I have had the honor at one time to be the president of the Academy of Ophthalmology and Oto-Laryngology, and I would therefore invite your especial consideration to this subject. I think very highly of this proposition. It would do a great deal to bring the different elements and societies together, and it might do us a great deal of good. We would derive a still greater benefit if we had a wider field to draw from. Therefore, I would suggest that someone make a motion that a special committee be appointed by the Chair to take this matter up and make such arrangements with the Academy of Ophthalmology and Oto-Laryngology as may further this purpose.

D. A. Kuyk, Richmond, said: It gives me great pleasure to move that the Chairman appoint a committee of three, looking to the furtherance and completion of the suggestions just made.

The motion was seconded and passed unanimously.

"How Far Should the Specialist in Rhinology and Otology Presume to Treat the Systemic Condition?" C. M. Cobb, Boston. Discussed by G. V. Woolen, Indianapolis; Sargent F. Snow, Syracuse; Schambaugh, Chicago; D. A. Kuyk, Richmond; W. Scheppegrell, New Orleans; Charles H. Baker, Bay City, Mich.; Joachim, New Orleans; Loeb, St. Louis; Crum, Utica; George L. Richards, Fall River, and Cobb.

"Report of Three Cases: 1. Case of Prolonged Intubation. 2. Esophageal Obstruction Due to Swallowing an Upper Alveolar Plate. 3. A Partial Extirpation of the Larynx for Carcinoma." George F. Cott, Buffalo. Discussed by B. R. Shurly, Detroit; D. A. Kuyk, Richmond; Otto T. Freer, Chicago, and Cott.

"The Early Manifestations of Laryngeal Tuberculosis: Their Recognition and Treatment." H. H. Briggs, Asheville. Discussed by Schuster, El Paso, Texas, and Briggs.

"The Immediate Relief of Hysterical Manifestations in the Larynx by Suggestion." H. W. Loeb, St. Louis. Discussed by D. A. Kuyk, Richmond; Hirschel, Spokane; J. F. Barnhill, Indianapolis; H. Dupuy, New Orleans; C. M. Cobb, Boston, and Loeb.

"Some Recent Experiences with Chronic Suppurations of the Ear." Philip Hammond, Boston. Discussed by H. Dupuy, New Orleans; Hirschel, Detroit; J. F. Barnhill, Indianapolis; C. M. Cobb, Boston; George L. Richards, Fall River, and Hammond.

The following committee was appointed by the Chair to consult with the Academy of Ophthalmology and Oto-Laryngology, as comprehended in the motion made by D. A. Kuyk: H. W. Loeb, St. Louis, representing the Academy; Sargent F. Snow, Syracuse, representing the American Laryngological, Rhinological and Otological Society, and C. H. Baker, Bay City, representing this Section.

THURSDAY, MAY 7—AFTERNOON.

The Section convened at 2:15 p. m.

The election of officers resulted thus: President, J. F. Barnhill, Indianapolis; secretary, Otto T. Freer, Chicago; member of House of Delegates, George L. Richards, Fall River, Mass.

"(*a*) The Distribution of Blood Vessels in the Labyrinth of the Ear, with Exhibition of Preparation and Drawing. (*b*) Wood's Metal Casts of the Middle Ear, with the Exhibition of Preparation and Lantern Demonstration." George E. Schambaugh, Chicago.

S. E. Solly, Colorado Springs, moved that the Section pass a vote of thanks for the beautiful exhibition of original work by Dr. Schambaugh. The motion was seconded by J. F. Barnhill, Indianapolis, and passed unanimously.

"Perisinusal Abscess of Lateral Sinus, with Metastases in Liver and Sterno-Clavicular Arthritis." Gordon King, New Orleans.

"Efficacy of Treatment of Acute Suppurative Otitis by Aseptic Drainage." H. Gradle, Chicago.

"The Great Value of Drainage and Ice in the Early Stages of Mastoiditis." Sargent F. Snow, Syracuse.

The above two papers were discussed by J. F. Barnhill, Indianapolis; Ledbetter, Birmingham, Ala.; Brown, Minneapolis; Hammond, Boston; George L. Richards, Fall River; C. M. Cobb, Boston; Hilscher, Spokane; D. A. Kuyk, Richmond; Donovan, Dubuque, Mont.; Stapler, Macon, Ga.; Gradle and Snow.

"Deformity of the Nasal Septum in Atrophic Rhinitis. Shall We Operate?" Kate W. Baldwin, Philadelphia.

On motions, duly seconded, the papers by Drs. Behrens and Joachim were read by title and referred to the Executive Committee.

Adjourned.

Section on Materia Medica, Pharmacy and Therapeutics.

TUESDAY, MAY 5—AFTERNOON.

The meeting was called to order by the Chairman, Solomon Solis-Cohen, at 2:35 p. m.

The Committee on Dosage of Liquid Medicines, Frank Woodbury, H. C. Wood, Jr., and A. Eshner, Philadelphia, made its report.

On motion the report was received and the committee discharged.

The Committee on Nerve Nostrums and Drug Addictions, A. W. Baer, Chicago; W. J. Robinson, New York, and H. C. Wood, Jr., Philadelphia, made its report.

On motion the report was received and the committee discharged.

The Secretary read a communication from the American Pharmaceutical Association, inviting this body to appoint delegates to the American Pharmaceutical Association.

The Chairman read his address.

The paper of Arthur R. Cushney, Ann Arbor, entitled "Is Pharmacologic Action Determined by Chemical Structure or by Physical Characters?" was read by Dr. Burdick.

M. Vejux Tyrode, Boston, read a paper entitled "The Relations Between the Pharmacologic Actions of Drugs and Their Therapeutic Indications."

The paper of Torald Sollmann, Cleveland, Ohio, entitled "Research Problems of Pharmacology," was read by the Chairman.

The paper, "The Physiologic Effect of the Ions," by Ralph N. Webster, Chicago, was read by title.

Discussion on all these papers was participated in by H. C. Beates, Philadelphia; W. J. Robinson, New York; W. W. Tompkins, West Virginia, and M. V. Tyrode.

A paper entitled "Mechano-Therapy, Massage, Bone Setting and Osteopathy," by John Madison Taylor, Philadelphia, was read by title.

On motion the recommendations of the Committee on Dosage of Liquid Medicines were adopted, as follows:

To the House of Delegates The following resolutions have been adopted by the Section on Materia Medica, Pharmacy and Therapeutics, and the delegate from that Section instructed to present them to the House of Delegates, with the recommendation that they be adopted by the Association:

Resolved, That teachers of medicine and pharmacy, editors of medical and pharmaceutic journals and authors of text-books are respectfully requested to give precedence to the metric method in the writing of all medical formulas and that, for the administration of doses of less than a teaspoonful, the quantity be stated in drops delivered from a standard medicine dropper or pipette of three millimeters external diameter, which will deliver twenty drops of water at 15 C., which will measure one cubic centimeter when dropped at the rate of one per second, and that the teaspoonful be considered as equivalent to five cubic centimeters and that the tablespoonful be considered as equivalent to fifteen centimeters; and

Resolved, That the orthography, abbreviations, etc., of the International Bureau, or as revised by the National Bureau of Standards at Washington, shall also be recommended for adoption in medical and pharmaceutic publications; and

Resolved, That a copy of these resolutions be transmitted to the Committee of Revision of the United States Pharmacopeia for 1900, with the request that they be incorporated, as far as possible, in the United States Pharmacopeia.

On motion the recommendations of the Committee on Nerve Nostrums and Drug Addictions were adopted, as follows:

To the House of Delegates: The following resolutions have been adopted by the Section on Materia Medica, Pharmacy and Therapeutics and the delegate from that Section to the House of Delegates instructed to present them to the House of Delegates.

In view of the spread in the growth of the use and abuse of proprietary remedies, the Section recommends:

1. That newspapers which do not print objectionable medical advertisements are entitled to and should receive the favor and preference of medical men.
2. That articles on the dangers arising from the use of quack nostrums should be written for such newspapers for publication.
3. That the Committee on National Legislation be asked to consider the feasibility of the introduction in the next House of Representatives of an interstate measure prohibiting or limiting the sale of poisonous and dangerous patent medicines.
4. That no medicinal preparation for internal use, as distinguished from antiseptics, disinfectants, cosmetics and dietetics, advertised as a remedy or cure to the laity, is entitled to the patronage of physicians, nor should such be admitted to the pages of the medical journals, nor to the exhibitions of the American Medical Association.
5. That manufacturers be requested to print the scientific or chemical names under the trade name of all pharmaceutic or chemical preparations.
6. That the general plan and object of the National Bureau of Medicines and Foods are entitled to a further careful investigation by a special committee of the American Medical Association.

On motion, Delegate Hill was instructed to present to the House of Delegates the recommendations of these committees.

On motion of Dr. Hill it was resolved that a committee of three be appointed, the Chairman to be one member, to draft a memorial to the Business Committee of the House of Delegates to oppose the contemplated change in the title of this Section by omitting the word "therapeutics."

The committee was Drs. Cohen, Beates and Hill.

The Chair appointed the Nominating Committee, as follows: Drs. Robinson, chairman, Tompkins and Slack.

C. A. Mayo, New York, delegate from the American Pharmaceutical Association to the Section, on invitation by the Chairman, briefly responded for this association.

Dr. Robinson moved that three delegates be appointed to attend the meeting of the American Pharmaceutical Association. [illegible] and carried.

On motion a resolution was adopted looking to the admission as associate members reputable pharmacists who are members of the American Pharmaceutical Association.

On motion, Dr. Hill was instructed to present this resolution to the Business Committee of the House of Delegates.

On motion adjourned to 9:30 a. m.

Wednesday, May 6—Morning.

The meeting was called to order by the Chairman at 9:50 a. m.

The minutes of the previous session were read, corrected and approved.

On motion the paper entitled "The Chemistry of Ergot," by A. B. Lyons, Detroit, was read by title.

Laura House Bronson, Iowa City, Iowa, read a paper entitled "Mercury." Discussion by Oliver T. Osborne, New Haven; W. J. Robinson, New York; W. W. Tompkins, West Virginia; S. Solis-Cohen, Philadelphia, and Bronson.

On motion W. S. Hall's paper was postponed to the afternoon session.

Arthur R. Elliott, Chicago, read a paper entitled "The Limitations of the Antidiabetic Diet." Discussion by H. C. Beates, Philadelphia; A. C. Croftan, Chicago; O. T. Osborne, Connecticut; W. J. Robinson, New York; W. B. Hill, Milwaukee; E. T. Shelley, Kansas; H. H. Moody, Alabama; G. W. Webster, Chicago; W. W. Tompkins, West Virginia; the Chairman, and A. R. Elliott.

It was moved that an effort be made to read and discuss all papers on the program by Thursday afternoon. Seconded and carried.

On motion adjourned to 2 p. m.

Wednesday, May 7—Afternoon.

Meeting called to order by Chairman at 2:15 p. m.

T. D. Crothers, Connecticut, read a paper entitled "Demonstrated Pathologic Effects of Alcohol."

O. T. Osborne, Connecticut, read a paper entitled "The Legitimate Therapeutic Uses of Alcohol."

Both papers were discussed by J. H. Musser, Philadelphia; J. A. Storck, New Orleans; W. J. Robinson, New York; A. C. Croftan, Chicago; C. S. N. Hallberg, Chicago, and the Chairman.

Paper by A. A. Eshner, Philadelphia, on "The Management of Fever in General," was read by title.

J. H. Musser, Philadelphia, read a paper entitled "The Therapeutic Value of Spinal Puncture for the Cerebral Symptoms of Typhoid Fever." Discussed by W. J. Robinson, New York; W. W. Tompkins, West Virginia; O. T. Osborne, Connecticut, and Musser.

J. A. Storck, New Orleans, read a paper entitled "Intestinal Antiseptics; Their Uses and Limitations." Discussed by O. T. Osborne, Connecticut; George F. Butler, Michigan; W. J. Robinson, New York; B. C. Keister, Virginia, and Storck.

W. S. Hall, Chicago, read a paper entitled "The Absorption of Iron from the Alimentary Canal." Discussed by G. F. Butler, Michigan; W. W. Tompkins, West Virginia, and C. S. Chamberlain, Ohio.

W. J. Robinson, New York, read a paper entitled "The Composition of Some of the So-called New Synthetics." Discussed by George F. Butler, Michigan; C. A. Mayo, New York; W. W. Tompkins, West Virginia; J. A. Storck, New Orleans; Rawlins, Tennessee; B. C. Keister, Virginia; C. E. Skinner, Connecticut; H. N. Leavell, Kentucky; C. S. N. Hallberg, Chicago; C. S. Chamberlain, Ohio; B. Pirosh, Chicago, and Robinson.

Dr. Storck moved that a committee of three be appointed by the Chair to consider the suggestion contained in Dr. Robinson's paper, with instructions to report to-morrow, with such recommendations as they may deem appropriate.

The Chair appointed Drs. Butler, Tompkins and Hallberg.

On motion adjourned to 9:30 a. m.

Thursday, May 7—Morning.

Meeting was called to order by the Chairman at 9:40 a. m.

Minutes of previous day read and approved.

N. S. Davis, Jr., Chicago, read a paper entitled "Exercise as a Mode of Treatment in Heart Diseases." Discussion by H. H. Moody, Alabama; W. W. Tompkins, West Virginia; the Chairman and Davis.

On motion, the paper entitled "Recent Advances in Actino-Therapy," by W. S. Gotthell, New York, was read by title.

Clarence E. Skinner, New Haven, read a paper entitled "Superheated Air in Therapeutics." Discussion by W. J. Robinson, New York; W. W. Tompkins, West Virginia, and Skinner.

C. S. N. Hallberg, Chicago, read a paper entitled "The United States Pharmacopeia." Discussion by W. J. Robinson, New York; J. V. Kelly, Philadelphia; Pirosh, Chicago; W. B. Hill, Wisconsin; O. T. Osborne, Connecticut; H. A. Moody, Alabama; F. Weber, Milwaukee; Chamberlain, Ohio, and Hallberg.

W. B. Hill, Milwaukee, read a paper entitled "The Limitations in the Use of Aconite and Veratrum Viride." Discussion by F. Weber, Milwaukee; H. A. Moody, Alabama; W. J. Robinson, New York; W. W. Tompkins, West Virginia; C. S. Chamberlain, Ohio; Kahle, Indianapolis; Leavell, Louisville; the Chairman and Hill.

Caswell A. Mayo, New York, read a paper entitled "Spurious Creosotes." Discussion by B. C. Keister, Virginia; W. W. Tompkins, West Virginia, and Mayo.

The following resolution was unanimously adopted:

Resolved, That, in the opinion of the Section on Materia Medica, Pharmacy and Therapeutics, the term "creosote" should be restricted solely to true wood-tar creosote, owing to the great danger arising from the present indiscriminate use of the term; and prescribers are requested to specify beech-tar creosote in order to properly distinguish the article from coal-tar creosote.

On motion adjourned to 2:30 p. m.

Thursday, May 7—Afternoon.

Meeting called to order by the Chairman at 2:35 p. m.

The Nominating Committee made the following report: For chairman, Oliver T. Osborne, New Haven, Conn.; secretary, Carl S. N. Hallberg, Chicago; delegate, W. J. Robinson, New York.

On motion the report of the committee was accepted and the officers nominated were declared elected.

George F. Butler, Alma, Michigan, read a paper entitled "Drugs Used in Nervous Diseases." Discussion by the Chairman.

Bittle C. Keister, Roanoke, Va., read a paper entitled "The Mind as a Causative and Therapeutic Factor in Medicine." Discussion by Ballard, Memphis; Slack, La Grange, Ga.; George F. Butler, Michigan; the Chairman; C. S. Chamberlain, Ohio; W. J. Robinson, New York; Betty, Memphis; W. W. Tompkins, West Virginia; H. A. Moody, Alabama, and Keister.

The committee appointed to report on the suggestions contained in Dr. Robinson's paper made the following report:

This committee, to which the paper of W. J. Robinson, New York, was referred, while fully agreeing with the sentiment expressed by the author, would suggest, in view of the present status of this question of proprietary medicine, that the paper may be so modified by the Editor of The Journal as to avoid any undesirable complications.

The committee, in view of the importance of the subject, respectfully makes these recommendations:

1. That, inasmuch as the primary cause of the proprietary medicine evils is the lack of knowledge on the part of medical graduates, the course in materia medica should be supplemented during the last year in connection with therapeutics by a course in pharmacy especially designed to qualify the student to formulate his own prescriptions in the most eligible manner.

2. A closer adherence to the United States Pharmacopeia and the National Formulary as a basis for text-books and instruction will lead to a greater appreciation of the official drugs and chemicals and formulas of the recognized medical authorities.

3. That some well-considered plan should be inaugurated for the differentiation of the thousands of medicinal articles and specialties to remove the present existing confusion among physicians and pharmacists alike, and to afford some kind of criteria to their ethical status, and to separate the true from the false.

4. That the revision of the patent laws, as applied to medicines, trade-marks and copyrights should be demanded.

5. That the primary object of a medical journal published by medical men or societies should be to chronicle the work of the profession it represents, and the general diffusion of medical knowledge, and not for the purpose of making money, commercial domination through the advertising privileges being derogatory to the profession.

6. It is recommended that a committee of competent persons be appointed to act as an advisory board in determining the limitations and privileges of advertisements appearing in The Journal and in the exhibits of the American Medical Association.

On motion the report and recommendations were adopted and the committee discharged.

The Chair announced the following delegates to the American Pharmaceutical Association: Hallberg, Robinson, Slack, Tompkins and Leavell.

The Secretary read a communication from the U. S. census office.

On motion the following committee was appointed to further consider the subject of suggestions contained in Dr. Robinson's paper and the report of the previous committee and report at the next session of this body, viz.: Moody, Robinson and Hallberg.

On motion a vote of thanks was tendered the trustees of the Carondelet Street M. E. Church for the use of their building; to the Committee of Arrangements and the medical profession of New Orleans and Louisiana for courtesies extended.

On motion a vote of thanks was tendered the Chairman and Secretary.

On motion adjourned, to meet in Atlantic City in 1904.

Section on Pathology and Physiology.

Tuesday, May 5—Afternoon.

Called to order at 2:30 p. m.

Address by the Chairman, Victor C. Vaughan of Ann Arbor, Mich.

Abstract of Papers 1 to S, being contributions from the Hygienic Laboratory of the University of Michigan, reported by Victor C. Vaughan, director.

(1) "The Chemistry of the Bacillus Coli Communis," by Mary F. Leach, Ann Arbor.

(2) "The Chemistry of the Bacillus Typhosus," by May Wheeler, Ann Arbor.

(3) "The Toxicity of the Intracellular Substance of Bacillus Typhosus," by Louis M. Gelston, Ann Arbor.

(4) "The Anthrax Toxin," J. Walter Vaughan, Ann Arbor.

(5) "The Intracellular Toxin of Bacillus Pyocyaneus," by Daniel McIntyre, Ann Arbor.

(6) "A Preliminary Chemical Study of the Hepatic Cells of the Ox," Frank Spencer and Frederick Munson, Ann Arbor.

(7) "The Toxicogenic Bacteria Found in Drinking Water," William G. Carhart, Ann Arbor.

(8) "The Chemical Tests for Morphin in the Presence of the Products of Bacterial Decomposition," by Myron W. Clift, Ann Arbor.

Discussion on the above by Henry A. Christian, Boston; A. C. Croftan, Chicago; W. S. Carter, Galveston; Joseph McFarland, Philadelphia.

The Secretary made announcement of the banquet.

Paper by Walter L. Bierring, Iowa City, Iowa: "Multiple Periosteal Sarcomata of the Cranium, with Involvement of Retroperitoneal Lymph Nodes and Attending Severe Anemia.

Appointment of Nominating Committee: E. R. LeCount, Chicago; W. L. Bierring, Iowa City; Frank B. Wynn, Indianapolis.

Discussion of Dr. Bierring's paper by E. R. LeCount, Chicago, and Henry A. Christian, Boston.

Wednesday, May 6—Morning.

Paper by E. A. de Schweinitz, Washington, D. C., read by Joseph McFarland, Philadelphia. Discussed by Dorset, Washington, D. C.; L. Hektoen, Chicago; Victor C. Vaughan, Ann Arbor; Joseph McFarland, Philadelphia.

Paper by Joseph McFarland, Philadelphia: "Studies of Antirennene." Discussed by L. Hektoen, Chicago; J. W. Foss, Phœnix, Ariz.

Paper by W. S. Carter, Galveston, Tex.: "The Protoplasmic Activity of the Renal Epithelium as Determined by the Elimination of Pigments Injected into the Circulation." Discussed by E. R. LeCount, Chicago.

Paper by L. W. Dean, Iowa City, Iowa: "The Influence of Consanguinity on the Organs of Special Sense, Especially on the Organs of Vision." Discussed by J. W. Foss, Phœnix, Ariz.

Paper by J. W. Foss, Phœnix, Ariz.: "Streptococcic Infection of the Lungs, Successfully Treated by Antistreptococcic Serum." Discussed by Guido Bell, Indianapolis; H. N. Graves, Georgetown, Tex.; W. S. Carter, Galveston; Louis Leroy, Nashville, Tenn.

Nominating Committee reported as follows: Chairman, Joseph McFarland, Philadelphia; secretary, Henry T. Christian, Boston; delegate, A. P. Ohlmacher, Gallipolis, Ohio, all of whom were elected.

WEDNESDAY, MAY 6—AFTERNOON.

Paper by J. M. Frazier, Belton, Tex. Discussed by H. B. Ward, Lincoln, Neb.

Paper by Henry B. Ward, Lincoln, Neb.: "Precision in the Determination of Human Parasites." Discussed by Frank B. Wynn, Indianapolis; W. L. Bierring, Iowa City; Allen J. Smith, Galveston, Tex.

Paper by Thomas S. Cullen, Baltimore, Md.: "Condition of the Endometrium in Case of Uterine Myomata." No discussion.

Paper by Louis Leroy, Nashville, Tenn.: "A Case of Aerogenes Capsulatus Infection of the Neck." Discussed by L. Hektoen, Chicago.

Paper by Henry A. Christian, Boston: "The Neuroglia and the Ependymal Epithelium of Teratoid Tumors." Discussed by L. Hektoen.

Paper by L. Hektoen, Chicago: "A Case of Short-Limbed Dwarfism," illustrated with lantern slides.

Paper by E. R. LeCount, Chicago, in the name of Peter Bassoe, Chicago: "A Case of Gigantism and Leontiasis Ossea," with lantern demonstration.

Paper by F. G. Novy and W. J. McNeal, Ann Arbor: "The Cultivation of Trypanosoma Lewisii." Discussed by H. B. Ward, Lincoln, Neb.

Adjourned, after vote of thanks to the retiring officers.

THURSDAY, MAY 7—AFTERNOON.

Paper by Newton Evans and F. J. Otis, Battle Creek, Mich.: "The Morphology and Biology of the Parasites of Blastomycetic Dermatitis," with lantern demonstration. No discussion.

Paper by Claude A. Smith, Atlanta, Ga.: "Further Observations of Ankylostomiasis in the South. Discussed by H. B. Ward, Lincoln, Neb.

Paper by J. G. Holmes, Chicago, read by W. S. Hall, Chicago: "The Working Capacity of a Muscle. Discussed by Henry Sewall, Denver.

Demonstration of new physiologic apparatus. Winfield S. Hall, Chicago.

On motion the following papers were read by title:

W. S. Newcomet, Philadelphia: "Tissue Changes under X-Ray Influence."

F. Robert Zeit, Chicago: "Endothelioma of the Uterus."

Final adjournment.

NAMES OF THOSE REGISTERED AT THE NEW ORLEANS SESSION.

We give below the names and residences of those who registered at New Orleans, at the fifty-fourth annual session of the American Medical Association. About 160 failed to indicate any preference as to sections. Through an error, discovered too late to allow a correct list to be prepared, these names were incorporated in the list of those registering in the Section on Practice of Medicine, but not in the summary below.

SUMMARY BY SECTIONS.

Section on Practice of Medicine	662
Section on Obstetrics and Diseases of Women	140
Section on Surgery and Anatomy	628
Section on Hygiene and Sanitary Science	25
Section on Ophthalmology	151
Section on Diseases of Children	44
Section on Stomatology	11
Section on Nervous and Mental Diseases	40
Section on Cutaneous Medicine and Surgery	28
Section on Laryngology and Otology	52
Section on Materia Medica, Pharmacy and Therapeutics	20
Section on Pathology and Physiology	32
Registered without expressing preference as to Section	160
*Miscellaneous	13
Total	2,006

* This includes those whose names or addresses it was impossible to verify and which have been omitted from the list of names below.

SUMMARY BY STATES.

Alabama	66
Arizona	3
Arkansas	46
California	24
Colorado	22
Connecticut	11
Delaware	2
District of Columbia	11
Florida	8
Georgia	27
Illinois	189
Indian Territory	7
Indiana	103
Iowa	73
Kansas	17
Kentucky	82
Louisiana	311
Maine	3
Maryland	22
Massachusetts	26
Michigan	73
Minnesota	37
Mississippi	101
Missouri	68
Montana	5
Nebraska	22
New Hampshire	4
New Jersey	18
New Mexico	3
New York	71
North Carolina	12
North Dakota	2
Ohio	139
Oklahoma	3
Oregon	2
Pennsylvania	114
Rhode Island	5
South Carolina	5
South Dakota	5
Tennessee	73
Texas	84
Utah	5
Vermont	6
Virginia	17
Washington	7
West Virginia	12
Wisconsin	62
Wyoming	1

The total registration in 1900 at the Atlantic City session was 2,019; in 1901 at St. Paul, 1,806; in 1902 at Saratoga Springs, 1,425; in 1903, at New Orleans, 2,006.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Pruritus.

Robin and Dalche, according to "Amer. Med.," recommend the following outline of treatment of pruritus occurring in women at the time of menopause or as the result of nervous disorders arising from rheumatism, gout, diabetes, Bright's disease or gastric disturbances: Locally prolonged applications of a 1 to 1,000 bichlorid solution, or 10 per cent. solution of chloral hydrate or a 5 to 10 per cent. cocain solution. The following powder may be used locally:

℞.	Pulv. orthoform		
	Pulv. diiodoform		
	Pulv. talci, āā	ʒii	8

M. Ft. pulvis. Sig.: Apply locally.

The statement is made that the anesthesia from orthoform lasts longer than that from cocain. They mention an application of ichthyol in 10 per cent. aqueous solution or in the form of an ointment of 15 per cent. strength; a 5 per cent ointment of methyl salicylate is also of service. The following ointment may be used:

℞.	Menthol	gr. 3/4	05
	Guaiacol	gr. v-xv	30-1.
	Zinci oxidi	ʒiiss	10
	Vaselini	℥i	30

M. Ft. unguentum. Sig.: Apply locally. The following is recommended for internal administration.

℞.	Erythrol	gr. ss-iss	03-.09
	Calcii fluorid	gr. ss-iss	03-.09
	Calcined magnes	gr. ii	12

M. Ft. chartula No. i. Sig.: One such after each meal. The foregoing is recommended particularly in fermentation *from* butyric acid. If lactic acid fermentation is present the following should be substituted:

℞.	Ammon. fluoridi	gr. iss-xv	09-1.
	Aquæ	℥x	300

M. Sig.: One dessertspoonful after breakfast and supper.

H. Leo, in an abstract in "Indian Med. Record," is inclined to the belief that pruritus generalized over the body may be due to an over-alkaline condition of the blood and recommends the following treatment: Hydrochloric acid (50 per cent.) *in* ten-drop doses every two hours. At the end of a few days the acid may be changed to a 1.5 per cent. solution of sulphuric acid, giving a teaspoonful every two hours. The urine in most of the cases in which this was tried was strongly *alkaline in* reaction previous to commencing the treatment.

Tuttle recommends the following *combinations* in the treatment of pruritus ani:

℞.	Benzoini	ʒss	2	75
	Hydrarg. ammon.	gr. xii		
	Lanolini q. s. ad	℥ss	15	

M. Sig.: Apply night and morning after thoroughly *cleansing* the parts; or:

℞.	Ext. hamamelidis flu.	℥i	30
	Ext: ergotæ flu.	℥iss	45
	Ext. hydrastis flu.	ʒi	4
	Tinct. benzoini co.	ʒiss	6
	Olei lini cum acid. carbol (5 per cent.)	℥i	30

M. Sig.: Shake and apply locally night and morning.

Lactic Acid.

Lactic acid is of great service as an intestinal disinfectant, according to Hayem in the "Indian Med. Rec." Especially is it of service in the green diarrhea of children, combined as follows:

℞.	Acidi lactici	ʒss	2
	Syr. ideai (raspberry)	ʒv	20
	Aquæ	℥iii	90

M. Sig.: One teaspoonful every two hours.

It may be given in the form of a lemonade as follows:

℞.	Acidi lactici	ʒiiss	10
	Syrupi	℥vi	180
	Aquæ	℥xxiv	720

M. Sig.: One-half a wineglassful several times daily.

It is also recommended in the treatment of infantile prurigo, in eczema, and urticaria, given in two to ten drop doses twice a day before meals. It is of service in typhoid fever and cholera and in chronic dysentery, in which latter case it may be given in fifteen-drop doses every two hours, gradually diminishing the number of doses until three are given daily. It must be well diluted in a mucilaginous mixture.

Phosphorus in Phthisis.

F. S. Plicque, in "N. Y. Med. Jour.," states, in cases of fever in tuberculous subjects accompanied by gastric disturbances, that the following is of service as a beverage:

℞.	Acidi phosphorici dil.	m. xxx	2
	Aquæ	℥xxx	900
	Syrupi	℥iii	90

M. Sig.: One or two quarts of this combination may be taken daily.

The following combination is recommended by Dujardin-Beaumetz as an agreeable preparation and taken by children readily:

℞.	Sodii phos.	ʒiss	6
	Potass. phos.	gr. xlv	3
	Syr. aurantii cort.	℥ii	60
	Vini Banyuls	℥vii	210

M. Sig.: A wineglassful after each meal.

Creosote may be given temporarily, but patients grow thin under its use as a rule. Brissonet recommends the following emulsion:

℞.	Creosoti phos. or tannophos.	ʒvi	24
	Syr. aurantii flor.	℥ii	60
	Mucil. acaciæ	ʒiiss	10
	Aq. aurantii q. s. ad	℥iv	120

M. Sig.: One teaspoonful three times a day after meals; or:

℞.	Creosoti tannophos.	ʒiiss	10
	Olei morrhuæ	℥viii	240

M. Sig.: One tablespoonful three times a day. These preparations, according to the author, are contraindicated in hemoptysis.

The phosphite of soda should never be given by the mouth because of its irritant action. It has a good effect on the fever and infection, according to the writer, and can be given in the form of an enema as follows:

℞.	Tinct. opii (Sydenham)	m. x		65
	Creosoti phosphiti	m. xv-xxx	1-2	
	Yolk egg	No. i		
	Olei olivæ	℥i	30	
	Lactis	℥v	150	

M. Sig.: At one dose introduced by the bowel.

Diarrhea.

R. Le Clerg, in "Rev. Med. de Normandie," recommends the following in the treatment of persistent diarrhea of endemic origin:

℞.	Naphthalin	gr. iiss		15
	Pulv. sacchari			
	Quin. sulph., āā	gr. iss		09
	Morph. hydrochlor.	gr. 1/15		004
	Essentiæ bergamot., q. s.			

M. Ft. capsula No. i. Sig.: One such capsule three times a day.

The treatment must be accompanied by a proper regulation of the diet.

Incompetent Heart.

R. C. Curtin, in "Internat. Med. Mag.," recommends the following combination in the treatment of anasarca and general dropsy due to a right heart incompetency:

℞.	Sodii benzoatis	gr. ii		12
	Tinct. digitalis	m. iii		20
	Spts. etheris nitrosi	m. xx	1	30
	Diuretin	gr. iii		20
	Spts. chloroformi	m. xv	1	

M. Sig.: To be taken at one dose and repeated every two hours.

To improve the hepatic circulation in such conditions, calomel serves the purpose best; however, blue mass, podophyllin, sodium phosphate or other cholagogues may be substituted for it.

Hysteria and Neurasthenia.

The following combination, containing the glycerophosphates, is recommended by Thompson, in "Med Rev. of Reviews," in the treatment of hysteria and neurasthenia:

℞.	Sodii glycerophosphatis	℥ss	15
	Calcii glycerophosphatis	ʒii	8
	Acidi phosphorici dil.	ʒvi	24
	Aquæ cinnamomi q. s. ad	℥iv	120

M. Sig.: One teaspoonful three times a day after meals.

Substitutes for Quinin.

According to Solis-Cohen, in "Amer. Medicine," euquinin may be used as a substitute for quinin. The advantages claimed for it are that it is practically tasteless, it causes no tinnitus aurium, less prone to disturb the digestion and is not so irritating to the kidneys. The following formula is recommended:

℞.	Euquinin	ʒi	4
	Ferri lactatis	ʒii	8
	Sol. acidi arsenosi	ʒiss	6
	Tinct. lavendulæ co.	ʒiv	15
	Elix. curacoa q. s. ad	℥iv	120

M. Sig.: One teaspoonful four times a day.

Administering Quinin to Infants.

According to an abstract in "Gaz. des Hopitaux," Borde states that quinin can be made so palatable that children will take it, by preparing a mixture as follows: Mix gr. 15 (1.00) of quinin sulphate with drams 2 (8.00) of olive oil. According to the writer twenty-seven minims, as measured in a graduate, will contain one grain (.06) of quinin. This oily mixture is then floated on a tablespoonful of cold milk; this can be easily swallowed by a child without detecting the taste of the quinin. The oily mixture can be given alone, as it rolls down the tongue and the taste is scarcely detected by the infant.

Removal of Corns.

The following combinations are of service in the removal of corns, according to the "Pract. Drug.":

℞.	Acidi salicylici	ʒi	4
	Acidi lactici	ʒi	4
	Ceroti simplicis	℥i	30

M. Sig.: Apply locally night and morning; or:

℞.	Acidi salicylici	ʒi	4
	Resinæ	ʒii	8
	Adipis	℥ss	15
	Olei amyg. dulcis	ʒii	8

M. Ft. unguentum. Sig.: Apply locally night and morning.

Heat Stroke.

Andrew Duncan, in "Tropical Medicine," states, in the preventive treatment of heat stroke, that the head and spinal cord must be properly protected, the dress must be loose around the neck, chest and abdomen. As curative measures, the patient should be moved into the shade, if possible, his clothes loosened and cold water poured on the head and neck, and frequently repeated. Ammonia should also be applied to the nostrils, a turpentine enema administered and a large mustard poultice applied to the chest. The author states that ice should not be applied to the head when the pulse is feeble and the skin cold. Chloroform is indicated if convulsions occur, administering only a few whiffs. If pains subsequently persist in the head, blisters should be applied to the nape of the neck and quinin given internally.

He states that a solution of trinitrin (1 to 1,000) is of service, giving 20 drops of this solution every quarter of an hour until the symptoms have disappeared. Venesection is not advocated on account of the great mortality following its employment. Anyone who has suffered from heat stroke should not visit the tropics.

Medicolegal.

Duty as to Providing Medical Attendance for Child.—While granting the existence of a legal obligation on the part of a parent, or one standing in the place of a parent, to provide medical attendance for a minor child, it seems to the second appellate division of the Supreme Court of New York that the obligation does not necessarily import in every case the calling in of a physician. In the case before it, of People vs. Pierson, the intention, it thinks, was to charge that the crime consisted not merely of a failure to furnish medical attendance generally, but a failure to furnish medical attendance by a qualified doctor. If this view of the indictment was correct, the court holds that it failed to charge a criminal offense, in the absence of an allegation or statement of facts showing that the case [alleged to be one of catarrhal pneumonia] was one in which a regularly licensed and practicing physician and surgeon ought to have been called. The question as to whether such a state of facts existed must be determined by the standard of conduct of an ordinarily prudent person. In other words, it is thought, the medical attendance which the law requires the parent to provide for his child depends on the circumstances of the case; that in some instances ordinary household nursing by the members of the family may be sufficient; that, if the illness is of a graver character, it may be enough to call in the services of a trained nurse, and, when danger is apparent, then the obligation, under the law, goes so far as to require that a physician be summoned. But the guide to proper conduct must be ascertained by asking, "What would an ordinarily prudent person, solicitous for the welfare of his child, and anxious to promote the recovery of the patient, do under the given circumstances of the particular case?" The accused, the court says, was not tried on any such view of the law as this. The trial judge told the jury that before they could convict him they must find "that he knew that the child was ill, and deliberately and intentionally failed or refused to call in a physician, or to give to it such medicines as the science of the age would say would be proper that a child in its condition should have." It was true that this portion of the charge presented alternatives, and imported that the accused might comply with his obligations under the law by giving proper medicines, even if he did not call in a doctor; but the court thinks it was going too far to imply, as did the language quoted, that he would necessarily fail to discharge his duty if the medicines he gave were not such as the science of the age would say were proper. As already intimated, it thinks the standard which should be applied was the conduct of an ordinarily prudent person. Nothing is said in the prevailing opinion about faith healing or anything of that kind, and no intimation is given that it was known to the court that the accused believed in it or for that reason did not summon a physician. Presiding Justice Goodrich, however, in a lengthy dissenting opinion discusses what he terms the underlying question of whether or not a profession of religious belief in Divine or faith healing justified the accused in his refusal to obey the statutory law of the state. He maintains that the cases which he cites establish the principle that a person who wilfully and knowingly refuses to furnish necessary medical attendance to his minor child, when he knows it to be dangerously ill, disobeys Section 288 of the New York Penal Code (which provides that a person who wilfully omits to perform a duty by law imposed on him to furnish medical attendance to a minor is guilty of a misdemeanor), without regard to the question whether or not he acted in obedience to his religious convictions, and that the statute is not offensive to the article of the constitution as to liberty of conscience.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

New York Medical Journal.

May 9.

1 *Presidential Address, American Medical Association: Medical Education in the United States. Frank Billings.
2 *Oration in Medicine, American Medical Association: Social Conditions in America in Their Relation to Medical Progress and Disease. J. M. Anders.
3 *Oration in Surgery, American Medical Association: Cancer and Immunity. (To be continued.) A. F. Jonas.
4 *Report of a Case of Pulsating Empyema Necessitatis, with Three Strongly Pulsating Tumors. Frederick P. Henry.
5 A Case of Epidural Abscess of Otitic Origin—Operation—Recovery. J. Guttman.
6 *Astigmatism Cured by Corneal Trauma. Percy Fridenberg.

1, 2, 3.—These articles appeared in The Journal, May 9.

4. **Pulsating Empyema.**—Besides the case here reported, Henry gives a general discussion of the subject and brief abstracts of a number of those reported in the literature.. From a careful study of many of the reported cases he concludes that the most important factors in the production of pulsating empyema are: Left-sided and large effusion; 2, relaxation of the thoracic wall from paresis of the intercostal muscles, and 3, a somewhat forcible heart beat. The presence of air in the pleural sac under great tension and the adhesion of the compressed lung to the pericardium are co-operating, but not essential causes.

6. **Astigmatism.**—Fridenberg first refers to Bull's case reported in the "New York Medical Journal" and abstracted in The Journal of February 29, ¶39, p. 541, and remarks that the tendency for the unexpected to happen is illustrated in his meeting, shortly after reading that account, with a case in which corneal astigmatism of low degree was neutralized by direct injury. He here reports the case. The mechanism was simple flattening of the corneal curve from the scar contraction. There was no actual section, but only a superficial, though extensive, incision of the cornea. Astigmatism was slight, and by peculiar chance just enough to neutralize the pre-existing inequality of curvature. He remarks that "the prophetic eye may see in the dim future the operation of graduated superficial keratotomy for astigmatism."

Philadelphia Medical Journal.

May 9.

7 *Presidential Address, American Medical Association. Frank Billings.
8 Report of a Case of Suturing the Omentum to the Abdominal Wall (Talma) for the Relief of Ascites Due to Cirrhosis of the Liver, Twenty-one Months After Operation. Thomas R. Neilson.
9 A Case of Cirrhosis of the Liver with Ascites; Operation Eight Weeks After First Occurrence of Ascites. Subsidence of Ascites Six Months After the Operation, and Non-Recurrence in Two Years. W. W. Keen and H. M. Fisher.
10 *Novelties in the Physical Treatment of Skin Diseases. L. Freund.
11 *Importance of Repair of Small Cervical Lacerations. James H. Burtenshaw.
12 *Toxic Amblyopia, from Wood Alcohol. J. W. Sherer.
13 *A Note on Traumatic Syringomyelia, with Report of a Case Presenting Sensory Disturbances Affecting One Limb, and Trophic Changes of the Subcutaneous Tissue of the Entire Limb. Alfred Gordon.

7.—This article appeared in The Journal, May 9.

10. **The X-Ray.**—Freund describes two new instruments for testing the penetrability and length of spark of the *x*-ray, the first consisting of a transparent scale of layers of aluminum and the second a scale "spintometer" arranged parallel to the tube and measuring the spark length. Still another apparatus is the Holzknecht chromoradiometer, based on the principle of the absorption of the *x*-rays by fluorescent salts, which produces reflections of a certain tint, which are compared with a standard color scale. (Illustrated in The Journal of Oct. 25, 1902, p. 1079.) Freund considers that the correct estimation of dosage and intensity and quality of the rays is not such an advantage in the treatment as might appear. We should study the individual reaction as well as action in these cases. There is a possible difference in individuals and the way they react to the rays. He has experimented with the

action of the ultra-violet rays and their bactericidal action and finds very little effect, but his investigations have shown that the heat rays exert a favorable influence in some skin affections.

11. **Cervical Lacerations.**—Burtenshaw calls attention to possible reflex effects of minute cervical lacerations which may be overlooked, and reports cases where they were hardly observable and yet operation caused almost immediate relief of symptoms. It does not follow that every tear of the cervix requires a surgical operation, but he thinks due significance is not given to the smaller ones, which in many cases are the unrecognized causes of not only local morbid conditions but of systemic ones as well.

12. **Wood Alcohol Blindness.**—Sherer reports a case and discusses the condition, pointing out the dangers of wood alcohol, and concludes that there is no remedy for this condition. He adds, in conclusion, a notice of Marlowe's researches on the pathology of the disturbance, which appears to be a primary destruction of the nerve elements.

13. **Traumatic Syringomyelia.**—In the case here reported by Gordon the symptoms were localized and unilateral, though in other respects most typical of syringomyelia.

Boston Medical and Surgical Journal.

May 7.

14 *President's Address, American Medical Association. Frank Billings.
15 *Oration in Surgery, American Medical Association: Cancer and Immunity. A. F. Jonas.
16 *Brachial Paralysis, Post-Narcotic. F. J. Cotton and S. W. Allen.
17 Pyronin-methyl Green: A Brilliant Double Stain for Cells and Bacteria. William F. Whitney.
18 X-Light in Anthropometrical Signalment. William Rollins.

14, 15.—These articles appeared in The Journal, May 9.

16. **Post-Narcotic Brachial Paralysis.**—After reporting four cases and analyzing the symptoms, Cotton and Allen emphasize particularly the following points:

> Paralysis of part or all the muscles supplied by the brachial plexus with some sensory involvement is not very uncommon after narcosis, though rarely mentioned. Its cause is not toxic but mechanical. It occurs only when the arms are long held above the head or lie in abduction—never if they lie flexed on the chest. The mechanism is a pressure on the nerve roots, probably between the clavicle and the muscles over the transverse processes of the cervical vertebræ, or from stretching over the head of the humerus in abduction.
>
> The trouble is essentially functional without known lesions. The lost function returns in part very early. Total recovery is often long delayed, but apparently is to be counted on. The possibility of the accident should be impressed on students, on house officers and on all of us. In view of this risk the arms of a patient under ether should always, where possible, be flexed with the hands on the chest. If other positions are unavoidable they should not be continued long without change.

Medical News, New York.

May 9.

19 *Oration in Surgery, American Medical Association: Cancer and Immunity. A. F. Jonas.
20 *The Resemblances of Malignant Endocarditis to Typhoid and Paratyphoid Infections. Henry L. Elsner.
21 *Nephrorrhaphy in Intermittent Hydronephrosis. J. Wesley Bovée.
22 Extraperitoneal Ligation of External Iliac for Femoral Aneurism. Wm. B. Crawford.
23 Intussusception: Report of a Case Reduced by Operation. George T. Vaughan.

19.—This article appeared in The Journal, May 9.

20. **Malignant Endocarditis.**—Elsner remarks that two facts especially impressed him in regard to the relations of malignant endocarditis to typhoid and paratyphoid infections: 1. The typhoid type of malignant endocarditis has rarely been diagnosed during life, and the detection of the focus from which the infection springs has presented the greatest difficulty. 2. In some cases the primary infection may be unnoticed or be so slight as to appear insignificant. He reports cases illustrating this point. Endocarditis of pneumonia is rather rare and it has special anatomical peculiarities. The right side of the heart is attacked more frequently and the aortic valve more often than the mitral. Endocarditis complicating pneumonia is sudden in onset and rapid in its course. He insists on the importance of the occurrence of chills as indicating secondary infection if the case is a primary typhoid, and also the importance of frequent examinations of the blood, not depending on the blood count alone. Repeated negative results of blood cultures do not exclude the presence of ulcerative endocarditis.

21. **Intermittent Hydronephrosis.**—The connection of intermittent hydronephrosis with mobile kidney is emphasized by Bovée, who reports two cases relieved by nephrorrhaphy, fixing the kidney in its normal position, thus straightening out the urethra and preventing temporary angulation which caused intermittent obstruction.

30 *Heredity, with Especial Reference to Certain Eye Affections. Francis Dowling.
31 The Country Doctor—My First Case of Labor in the Country. John G. Albers.
32 Surgery of Prostate, Pancreas, Diaphragm and Spleen. (Continued.) B. Merrill Ricketts.

30. **Heredity.**—Dowling discusses heredity in general, especially in its relation to eye disorders. He finds pathologic hereditary transmission particularly marked in cases of certain eye affections. In many instances the morbid processes are latent and require some external injury to serve as an exciting cause for their development. To this class belong myopia, cataract, glaucoma, etc., though some of these may be present at birth. As a rule the hereditary affections are probably the result of fetal disease. Another class of inherited eye diseases belong to those maladies which the parents transmit to their offspring in the shape of a dyscrasia, such as the tuberculous, the scrofulous, the syphilitic, etc., which lay the foundation for various eye affections. In this connection, also, he mentions consanguinity and the frequency of retinitis pigmentosa in these cases, besides myopia, color blindness and ordinary blindness. He especially calls attention to the part the color of the eye seems to play. Dark eyes are seemingly the most subject to these hereditary disorders.

34 *A Certain and Permanent Cure of Painful Tic—Tic Douloureux. J. K. Bauduy.

34. **Tic Douloureux.**—The Dana method of administering progressively increasing and massive doses of strychnia is endorsed in neuralgia by Bauduy. He has tried this, using an auxiliary nerve food with great success. While he admits that strychnia needs to be used with caution and the effects watched, he has employed it by the mouth, gradually increasing the dose until 1/10 of a grain three times a day was used for some time in connection with the anode galvanic treatment to the nerve, and with arsenic and iodid of potassium. He is convinced that it will accomplish radical cures.

36 *Illuminating Gas Poisoning. Paul M. Pilcher.
37 *Causes and Relief of the Summer Mortality Among Brooklyn Children. C. LeGrand Kerr.
38 The Etiology of Insanity. R. C. F. Combes.

35. **Congenital Hypertrophic Stenosis of the Pylorus.**—Shaw gives the history of the recognition of this condition and describes its symptoms. It is usually fatal in the ordinary type in about ten to fourteen weeks. He recognizes, however, two other varieties of the same pathologic condition, one of

which is the so-called congenital spasm of the pylorus, first suggested by Thompson of Edinburgh and assigned by him as the primary cause or etiologic factor of pyloric hypertrophy. In these cases recovery usually occurs in a few days without operation. In the second type the stenosis appears at four or five years and upwards and he reports cases which he thinks may be classed under this head—an incomplete stenosis with only occasional spasm, but complete closure coming on gradually. He also reports two cases of partial pyloric hypertrophy in which spasm appeared to predominate. Excepting in such cases as the last two reported, the only successful treatment is operative. In nearly all any other measure is not lasting. In conclusion he says that cases of sudden and persistent vomiting occurring soon after birth without any ascribable cause, resisting all treatment, should be looked on with suspicion and receive at least a provisional diagnosis of congenital pyloric stenosis. Similarly, disease of the pylorus ought to be suspected in case of cyclic vomiting extending over several years.

36. Illuminating Gas Poisoning.—Pilcher has had a number of cases of this condition under his care and reports several in detail. He holds that the toxic effects of illuminating gas are primarily due to chemical changes produced in the constituent elements of the blood, this being a substitution of carbon monoxid hemoglobin for the oxyhemoglobin, so diminishing the supply of oxygen to the tissues. The direct cause of most of the symptoms is diminished percentage of oxygen in the arterial blood supplying the central nervous system. This would indicate a treatment by the administration of pure oxygen in order to force it into simple solution in the blood and so reinforce the remaining oxyhemoglobin. For the further purpose of supporting the circulation, diluting the poison, assisting its elimination and its possible influences in breaking up the chemical combination of the CO with the hemoglobin, a copious infusion of normal salt solution should be administered. In severe cases direct blood transfusion should be practiced. To control the tendency to acute cardiac dilatation, a free use of cardiac stimulants should be early resorted to. Edema of the lungs is the chief of the secondary sources of danger and must be constantly watched for and every possible measure taken to guard against it.

37. Infant Mortality.—Kerr reviews the statistics of infant mortality in Brooklyn and calls attention to the defects which increase it. He thinks the chief needs are a rigid supervision of all cases of pertussis, a recognition by the public of the dangers of neglected cases of measles, cleaner streets, more care in the preparation of the infant's food and, most of all, a good, wholesome, clean milk supply on which the physician can absolutely depend for his modifications.

48 *A Contribution to the Study of the Human Blood Pressure in Some Pathological Conditions. George W. Norris.

41. Pronation of the Foot.—Huhner describes this condition, which is not flat foot, but has been called weakened foot or weak ankle. The head of the astragalus rotates inward and backward, its body forward and outward, and the internal malleolus moves backward and the external forward. The front part of the foot is abducted as a whole, and the calcaneum rotates toward a valgus position. In this condition care should be taken as regards footwear. Sometimes raising the inner side of the shoe will be all that is needed. Tip-toe exercises should be given to strengthen the adductors and external rotators of the foot. For mechanical support he advises an apparatus devised by Lovett and Cotton. He finds this condition very frequent, about 64 per cent. of males and nearly 80 per cent. of females are thus affected.

43. The Opium Habit.—The opium habit is considered by Jelliffe as probably very frequent and in its psychology having a parallelism with the alcohol habit. The idea that it is incurable should never be accepted by the medical man. There are great variations in the cases. Some patients can voluntarily give up the habit while others do not care to. The cardinal principles on which a rational therapy are to be founded are, he thinks, the substitution of different ideas by suggestion and of different sensations by other drugs. His experience is that hyperbromidization according to Macleod's method is best. His experience with the hyoscin treatment of Dr. Lott is rather contradictory. In one or two cases it has given him an unpleasant shock from dangerous collapse during its administration. Heroin, he thinks, may be a useful drug in these conditions in many cases, though he does not consider it reliably efficient. Several cases are reported.

45. Typhoid Perforations.—The frequency of this condition is estimated by Briggs as very great. With a death rate of 10 per cent. there would be 50,000 mortality per annum from typhoid in the United States, and perforation causes about one-third of these deaths, giving, therefore, a death rate of something over 16,000 or 17,000 cases of typhoid perforation per annum. The usefulness of operation has become established of late years and operative technic is probably nearly perfected; improvement will be along the line of early and accurate diagnosis. The mortality following operation is not, he thinks, altogether due to general peritonitis. It is important to distinguish between the symptoms and signs of the condition. Of the symptoms, abdominal pain is the most important when present. Spreading sensitiveness is a little more to be relied on than spreading pain. The sensations associated with shock are of considerable importance, but their absence may be disregarded in making the diagnosis. Of the physical signs, muscular resistance is probably the most important. Distension and tympany are not of any consequence as regards perforation *per se.* The presence of *abdominal gas outside the intestine,* if it can be determined with absolute certainty, is practically a proof of the perforation. Nausea and vomiting are so rare that they are of little aid. Altered respiration is a sign of some consequence and is probably to be interpreted as is muscular resistance, namely, a means of protecting the abdomen. Alteration in temperature may be of some value, but its absence is not conclusive of anything. The pulse is of great importance; it is, of course, an evidence of systemic shock accompanying perforation, but otherwise deserves special attention. There is almost invariably a rise of perhaps twenty beats or more and the occurrence is rather sudden, the quality altered, the tension reduced and the pulse rendered readily compressible. Any sudden marked alteration in the rate and quality is an indication of importance. We know too little as yet of the altered blood conditions. If the diagnosis of hemorrhage is incorrectly made, and, instead of this, perforation has occurred, the desirable opportunity for operation is lost while waiting for demonstration of hemorrhage through the bowel passages. The red count and hemoglobin percentage may, therefore, be of some use. Systemic shock is a matter of very great importance. He sums up the signs and symptoms on which we must mainly rely as pain, sensitiveness, muscular resistance, altered respiration, alteration in rate and quality of the pulse and evidences of systemic shock. The differential diagnosis is discussed at some length. As for treatment, operation is necessary, the sooner the better. Attention must be paid to anesthesia, especially as to the reduction of systemic shock. In some apathetic and stolid patients local anesthesia may be best. Briggs doubts, however, whether the extensive and careful abdominal irrigation usually required can be as well accomplished without general anesthesia. Careful, not too hurried, operation is advised and drainage. The question of exploratory incision is, he considers, of the greatest importance. Where perforation is suspected with a not absolutely certain diagnosis, exploration affords the only hope of avoiding a possible catastrophe. The improvement in recovery rate after operation, though as yet not high, is certainly encouraging. In conclusion, he insists on the great value of complete postmortem examinations in all these cases as being more instructive than reports of recovered cases. A complete examination, however, does not mean a complete autopsy.

48. **Blood Pressure.**—Norris discusses the blood pressure in various conditions of disease, such as nephritis, saturnism, heart disorders, cardiac lesions, etc., quoting extensively from the literature. He says:

> In the present state of our knowledge the height of the blood pressure can not be said to be a useful index in regard to the potency of the systemic circulation, nor is it a criterion of sufficient constancy to be used as a basis for prognosis. The pressure index may, in some instances, be regarded as a relative indication for treatment. What, as a rule, we require to know is not so much the actual height of the tension as the amount and character of its fluctuation. We have seen that a fair state of nutrition may be carried on in the convalescence from typhoid fever with a tension of 85 mm. and in arteriosclerosis at 180 mm.

53 *The Advantages and Limitations of the Rest Cure. George F. Butler.
54 The Non-Surgical Treatment of Epithelial Disease. J. J. Moore.

51. **The Blood in Pregnancy and the Puerperium.**—From a study of the literature and personal examinations, Pray concludes that while blood generation fails to keep pace with the increased vascular area, a serous dilution of the blood takes place. Ordinarily this is not serious and can be overcome by proper hygiene, fresh air, attention to exercise and food and avoidance of constipation. If the vitality is overtaxed, the increased demand of nutrition may call for iron or other tonic treatment. The regeneration of the blood is partly effected by the lessening of the vascular area after labor and subsequent transudation of fluids into the tissues. The leucocytosis is due to increased action of the enlarged lymph glands of the pelvis, and in part to the increased metabolism which causes a somewhat toxic action. The lochia aid in its decrease. The persistence is accounted for by the fact that the involution of the hypertrophied pelvic organs and breast is accomplished in a great measure by the leucocytes. The blood after cesarean section shows the same general conditions as after normal labors.

53. **The Rest Cure.**—Butler's paper is largely a criticism of the methods of the Weir-Mitchell rest cure, which he thinks has to some extent gotten into the hands of those who use it in an unethical way. He also thinks that Mitchell has overestimated the value of overfeeding and underestimated the importance of suggestion. The Playfair school as a badly modified offshoot of the Mitchell school has the same bias; mere alteration of environment is not change. There is danger from the nurses, especially if trained in general hospitals. They are likely to examine for symptoms and suggest them to the patient, thus increasing the introspective tendency. They are also fond of impressing the patient with their importance by narrations of medical and surgical cases which suggest uncomfortable imaginations and increase the nosophobia. The patient needs reassurance rather than conviction as to his case. Intellectual cultivation through reading by the nurse, and cheerful yet logical conversation by the physician on the source and character of the patient's fears are excellent means of combating the distressing mental conditions of rest cure patients. Another error prominent in ordinary rest cures is that in dietetics. The patient, not the disease label, must be considered. While milk is valuable, it will cause gastrointestinal catarrh in many cases and buttermilk might often take its place, but is forbidden by many physicians. The necessity for hot and cold baths is mentioned, but the patient's disinclination for them is generally humored. Massage, which simply supplies the place of exercise, is too often given under the pretense of some occult, magnetic, osteopathic or hypnotic influence. Under these guises it is positively harmful and a mental and physical poison. The masseur needs to be kept in his own place and is too apt, like the nurse, to prescribe, diagnose and give clinical lectures. Some masseurs, Butler says, are perverts, hence proper selection and strict supervision of masseurs and massage is imperatively necessary. Electricity has the same ill effects unless it is explained to the patient. It is simply a delicate localized form of exercise. The medicinal treatment in the rest cure should be minimal and directed only to symptomatic indications which can not be overcome by the proper bowel, bladder and uterine hygiene, diet, massage and electricity. There is too much use of the bromids, for which Mitchell is partially responsible. The bromid, chloral and other drug habits are sometimes created through rest cures, and this possibility receives too little attention. Another necessity in the rest cure is that of bringing about periodic functions in the gastro-intestinal canal. It should be looked on as a method of education of the system, not merely as a therapeutic measure.

62 Septal Fallacies. Beaman Douglass.

55. **Local Anesthesia in Surgery of the Upper Air Passages.**—Bodine insists on the importance of regarding the psychic element in local anesthesia of the upper air passages. He describes the methods of using cocain and claims that many symptoms thought to be due to cocain idiosyncrasy are only manifestations of nervous fright. In some cases, of course, application to the mucous membrane is alone possible, but it is not an entirely satisfactory method. He notices in conclusion the Crile method of "blocking" the nerve, thus cutting off the reflexes from and anesthetizing its territory.

56. **General Anesthesia in Operations on the Upper-Air Passages.**—The difficulties of operating in the upper-air passages on account of the necessity of having free respiration at the same time, etc., are noticed by Bennett, who then discusses the different anesthetics employed. He thinks that while nitrous oxid has the best record for safety, that if it were used for long operations this would not be the case. The greatest contraindication to its use is the mechanical obstruction to respiration. For prolonged operations ether is the safest and should be preceded by nitrous oxid when possible. Chloroform is the most dangerous. Its increased mortality, he thinks, is due almost entirely to the following factors: 1. Unusual position, of which sitting is the most dangerous; 2, interference with respiration; 3, sudden hemorrhage, usual in many nose and throat operations. By the avoidance as far as possible of these dangerous factors he thinks that chloroform can be employed with reasonable safety. It should be preceded, if possible, by ether or gas or gas and ether. The ether or gas and ether is probably the best for prolonged operations in the removal of tonsils or adenoids. Some children are not capable of being sufficiently long anesthetized by the nitrous oxid alone. The use of ether stimulates the patient and a slow recovery of consciousness is of advantage in sparing the patient the sights and sensations which must accompany the first moments after the removal of tonsils or adenoids. Ether increases the tendency to immediate hemorrhage. If chloroform is used it should be administered sparingly, the head kept

low and respiration interfered with as little as possible. Bennett prefers full anesthesia in these cases. Protection of the lower-air passages from entrance of foreign matter is one of the most important matters in operating on the upper-air passages. In ordinary cases without tracheotomy danger from this source is prevented by frequent swabbing of the throat during the operation, by the placing of pads to receive matter passing toward the lungs, by the position of the patient and by a degree of narcosis in which the patient protects himself by coughing and swallowing. In conclusion, he remarks in regard to a method of giving anesthesia devised by Crile, completely protecting the lower-air passages by introducing heavy walled rubber tubes through the nostrils to a point in the pharynx opposite the top of the larynx, respiration taking place through the tubes and the anesthetic applied in this manner, while the mouth is kept opened, the tongue pulled well forward and the space thus formed at the back of the pharynx is packed tightly with gauze. In the cases where he has used this method of protection of the lower-air passages it has been absolute, the respiration has been normal and the narcosis perfect.

58. **Acute Laryngitis of Singers.**—After first noticing traumatic laryngitis, Curtis remarks that the most common cases are of nervous origin due to mal-coördination of the intrinsic muscles from perverted inhibitory function, or paresis of the motor nerves, and nearly always accompanied with congestion. We must observe the shape of the glottic chink. A unilateral adductor paralysis should at once lead us to a guarded prognosis. We should watch in deep respiration to see if paralysis is complete. Bilateral adductor paralysis is generally functional in origin, due to hysteria or reflex causes, but in almost all the laryngeal inflammations we notice some paresis of the lateral arytenoid muscles. In abductor paresis we have an affection of the crico-arytenoid postici muscles frequently due to pressure on the recurrent nerves from enlarged bronchial glands, or disturbance of the vagus. This is often produced by a simple cold. But the most common of all the pareses accompanying a laryngitis is paresis of the thyro-arytenoid internus and externus muscles. The elliptical chink of the glottis caused by a paresis of the internal thyro-arytenoid is familiar. Less frequent are those where the cords are deflected posteriorly to the right or left side or there is a double ellipse caused by combined paresis of the arytenoid and the external thyro-arytenoid muscles. The patient almost always presents himself trying to talk in a loud tone with a very husky voice. The first thing in treatment is to insist on absolute silence, or a tone whispered on the lips with no laryngeal quality in the voice. This must be enjoined, until the sound written "humph" may be made without effort through the nose, the mouth being closed. Then he commences vowel exercises, using words like ming, mong, ding, dong, maw. mow, etc., as an adjunct to treatment. The instant innervation is re-established, muscle exercises to overcome the slight infiltration may be employed. From the first he gives strychnia internally and applies static or faradic electricity along the course of the recurrent laryngeal nerves. Adrenalin chlorid solution sprayed into the larynx before tone exercise is commenced is very useful. He also alternates the exercises with massage each side of the trachea and thyroid as well as under the ramus and angle of the jaw. A cold pack is then applied to the throat and the pyriform sinuses are swabbed with tincture of iodin and glycerin in equal parts, to stimulate the nerves and produce a counter-irritation without the vocal larynx. Nutrition and elimination must be looked after. The respired air must be cold and pure. Later, after the laryngitis has been relieved, he would use a spray of 1-1,000 solution of adrenalin in four volumes of water during a performance, alternated with an inhalation of menthol in albolene (5 to 10 grs. to the ounce) or an inhalation of iodoform in ether. He has saved many performances by using this method and considers it the simplest and best.

60. **Acute Mastoiditis.**—McCaw has found no reference in the literature to the influence of acute mastoiditis on audition, and gives his views on the subject. His conclusions are offered as follows:

> 1. Great reliance can be placed on abortive measures in the hemorrhagic variety of acute tympano-mastoiditis following influenza, with a reasonably certain prognosis of normal hearing. In no other form of the disease can this be done. 2. The period of the disease at which appropriate treatment is applied influences the ultimate functional result. 3. In all cases requiring operation the earlier we attack them surgically, the greater will be the amount of hearing preserved. 4. The dry method of post-operative treatment seems to influence the function of audition, but to a less extent than early surgical interference.

61. **Ear Diseases.**—Stirling finds that nasal treatment is unprofitable to the patient in case of pure sclerosis, and that in aural catarrh it should be limited to removal of the conditions which may be interfering with recovery of the mucous membrane lying between the nose and tympanum. A nasal operation for the sake of the ear should be one that is advisable for the sake of the nose. In a few cases of slight adenoids situated around the orifice of the eustachian tubes it may be advisable to remove them, even when there may be few or no symptoms referable to the nasopharynx.

72 *Treatment in Gynecology from a Medical Standpoint. Mary Gage-Day.
73 *The Roentgen Ray in Obstetrics. Joseph B. Cook.

68. **Pneumonia.**—Livingston recommends the use of ergot in pneumonia on the ground that the principal underlying condition in the disease is dilated blood vessels and that ergot is the only general equalizer of the circulation. He claims that if called sufficiently early, while the disease is still a matter of congestion, all that is needed is a hypodermic syringe and a solution of ergot, and that the free use of the drug in the first stage will abort, cut short or markedly limit the extent of the second stage and also guard against complications of the disease. He discussed the subject and the mode of administration in THE JOURNAL, March 21, 1903, p. 774.

69.—This article has appeared elsewhere. See THE JOURNAL of May 9, ¶32, p. 1323.

71.—See abstract in THE JOURNAL, xxxix, p. 1204.

72.—Ibid.

73. **X-Rays in Obstetrics.**—Cooke reviews the possible use of the Roentgen ray in obstetric cases and deduces the following conclusions:

> The value of the *x*-ray for studying the dimensions of the pelvis is, for practical purposes, lost, because of the difficulties attendant on its use, and at best it is probably not so reliable as mensuration and palpation performed by the skilled observer. In the study of the gravid uterus the results are wholly unsatisfactory when compared with those obtained by the ordinary recognized methods of examination. As a means of diagnosing certain forms of ectopic gestation fairly reliable presumptive evidence may possibly be secured, but it would need the corroboration of more positive methods before it could be definitely accepted. Advanced pseudocyesis could doubtless be detected by the use of the *x*-rays, but the administration of a little chloroform would accomplish the same result in a far simpler manner. In suspected twin pregnancies, where diagnosis can not be made with certainty, the *x*-ray may have a distinct diagnostic value, and would doubtless be of assistance in these rare conditions.

77 *The Intravenous Injection of Formaldehyd as a Cure for Septicemia and Its Use in Smallpox. Nelson D. Brayton.

77. **Formaldehyd in Septicemia.**—Brayton has investigated the use of formaldehyd in smallpox and notices its advantages in variolous septicemia. He has collected the history of the use of formalin infusions in five different cases, all fatal, and does not believe that any germicide can be introduced into

the vascular system in quantities sufficient to destroy the germs without being destructive to the delicate tissues with which it comes in contact, and, inasmuch as effective dilution would necessarily be fatal to the patient, its use is contraindicated. For the present we should confine ourselves in the severer forms of sepsis to the use of normal salt solutions or those more nearly conforming to the constituents of the blood plasma. The response to the infusions in the cases described was quick and remarkable, illustrating the necessity for the addition of fluids to the blood in pustular smallpox.

Annals of Gynecology and Pediatry, Boston.

78 *The Scope of the Vaginal Incision. Andrew F. Currier.
79 *Cancer of the Cervix; Treatment by X-Ray. Thomas P. Scully.
80 *Hyperplasia and Hypertrophy of the Uterus. Charles G. Geiger.

78. **Vaginal Incision.**—The usefulness of anterior or posterior vaginal incision is discussed by Currier and the posterior incision with its modifications has, he thinks, the greatest sphere of usefulness. Why section of the peritoneum by way of the vagina should make less impression on the vitality of the individual than that made through the abdominal wall has never been explained, but it is recognized as a fact. Hemorrhage after vaginal operation is more easily controlled; there is less danger and the elimination of a possible hernia later is of some importance. The anterior vaginal incision may be made for certain diseases and dislocations of the uterus, for certain diseases of the tubes and ovaries and occasionally for the treatment of inflammatory pelvic exudates. The most frequent indication is retroflexion and it will often be found useful in cases where tuberculosis or serious heart disease or disease of the liver or kidneys renders pregnancy undesirable, and in which the fallopian tubes may be ligated to prevent it. Myomata of the anterior wall of the uterus can be removed in this way. It also will occasionally be a valuable aid in the diagnosis of disease conditions in the anterior segment of the pelvis. The posterior incision is indicated under the following heads: 1. Diagnosis; 2, pelvic exudates; 3, tumors of the appendages; 4, pediculated myomata; 5, intraligamentous cysts; 6, displacements of the uterus and appendages; 7, accumulations of blood in the pelvic or abdominal cavity, not encapsulated or isolated; 8, some of the exigencies of parturition and the puerperal state. This enumeration shows it has a very broad field of usefulness. Details of its application are given.

79. **Cancer of the Cervix Treated by the X-Rays.**—Three cases are reported by Scully, all of which were greatly relieved and apparently well on towards recovery. He has two other cases still under treatment.

88. *Diabetes.*—The dietetic treatment of diabetes is discussed by Vaughan, who mentions his tests for sugar. He prefers Trommer's with Fehling's solution, and if there is no reduction sugar is probably absent, but to confirm this Nylander's test may be used. Where both or either of the preceding reactions have been positive, but not prompt and convincing testimony, he also employs the fermentation test, using a control test with normal urine at the same time, and finally, he often seeks confirmatory evidence with the phenylhydrazin test. Having ascertained that the patient is diabetic the question is how far he has lost his capacity of using carbohydrates, and for this purpose he has a graduated diet table for one week in which the carbohydrates are decreased from 330 grams per day to nothing on the seventh day, with a corresponding increase of fats and proteids. The table differs somewhat from those generally prepared in containing relatively more fat and less proteids. When the patient has reached the bill of fare prescribed for the seventh day he usually continues this for five days, during the last two of which the urine should be collected and tested for sugar. If it has disappeared from the urine under this diet, the case comes under the head of what is generally known as mild diabetes. Occasional tests are made to see the amount of carbohydrates that can be consumed without the reappearance of sugar, and then a steady diet is fixed according to the findings. There are certain difficulties, but this plan seems to him the best. He includes in his diet list a certain amount of wine, and says that in this disorder a certain amount of alcohol is often useful. As regards the difference between the mild and severe forms of diabetes, he thinks it is merely one of degree. The patient with mild glycosuria who allows himself to indulge in an excess of carbohydrates is likely to find himself sooner or later the victim of the grave form of the disease. For details of the diet table the reader is referred to the original article.

1. Arm After Resection of Scapula.—Quenu removed the entire scapula from a youth of 16, on account of an osteosarcoma, in October, 1902. He gives 8 cuts showing the fine functioning of the arm at present and the radiographic findings. He has found 38 similar cases in the literature in which the scapula had been removed on account of a malignant tumor with retention of the arm. In 25 cases the results have been highly satisfactory and in all of this number fixation of the humerus had been included in the intervention. This was realized by cicatricial adhesions from the long suppuration in the earlier cases, and in the others by preservation of the acromion or suture of the remnants of the capsule, either to the clavicle or to its ligaments, thus re-establishing the muscular attachments. It is not always easy to re-establish the continuity of the muscles, but it must be done as far as practicable. By operating on these principles the arm will be firm and freely movable. Eight at least of the cases he cites are American.

2. Tavel's Salt-Soda Solution.—In 1892 Tavel recommended a saline-alkaline solution as superior to the physiologic salt solution for flushing and sterilizing purposes, on account of certain of its properties. It induces a slight irritation which elicits leucocytosis and phagocytosis, and thus favors the healing of wounds. He never recommended it for subcutaneous or intravenous injection and deprecates such a use for it.

3. Appendicitis and Opium.—Krafft points out that when a physician refers to appendicitis he has in mind an inflammation of the mucous lining, while the surgeon always means inflammation of the serous membrane. Much confusion would be avoided if the latter would say "periappendicitis" instead of "appendicitis." Inflammation involving the surrounding parts is more than mere appendicitis. Krafft further argues to prove that purgatives and rectal injections are dangerous in periappendicitis, as the peritoneum, which is always inflamed in this condition, is hindered in its task of encapsulating the lesion if it is shaken and disturbed. Surgeons do not give opium to cure the periappendicitis, but merely to soothe the pain and reduce peristalsis while waiting for the operation. The latter is the only rational treatment, and opium is an adjuvant for it. It relieves the patient and, by resting the intestine, favors the formation of adhesions. Injections and purgatives are useless and may be dangerous. They should always be proscribed the moment the physician notes a sensitive area at McBurney's point. Until the tenderness develops, the case belongs to the physician, as it is still in the mucous membrane stage, and purgatives, injections and other measures to disinfect the large intestine and its adnexa may ward off eventual periappendicitis, but so soon as tenderness at McBurney's point is discovered, the surgeon should be called in to superintend the further developments.

4. Ligature of Vena Cava.—Houzel reviews the history of ligatures of veins, especially of the inferior vena cava, and describes a personal case in which it was successfully done. He also quotes in full Bottini's similar operation and a third one by Schede, in which the patient succumbed eighteen days later. In his own case the inferior vena cava was torn during a nephrectomy for an old, large pyonephrosis. The patient was a woman of 36, a street vender, otherwise healthy. The vein was the size of a thumb, clinging close to the spine, and was torn for about 1 cm., the blood spurting as if from an artery. A catgut ligature was applied above and below the tear, just beyond the forceps on each side. The renal vessels were each ligated separately and the kidney removed entire, without escape of pus. Except for a slight, transient edema of the legs, no disturbances were noted from the complete arrest of the venous circulation in the cava, either in this case or in Bottini's. In Schede's case a lateral suture was applied, not a ligature. Theoretically, this is the preferable intervention, but his patient died, while the two others recovered. The autopsy showed fatty degeneration of the heart, with slight constriction at the point of the suture. Lateral suture exposes to the danger of thrombosis or embolism. Purpura experimented on dogs, and found that abrupt ligation of the vena cava was always fatal, but that if the vein were first constricted for a time and then ligated, the animals bore the intervention without apparent injury. In the cases above described the circumstances were probably of the same character. The pressure of the tumor had compressed the vein and thus prepared it for successful ligation. In Bottini's operation a portion of the vein was resected adherent to the tumor, a lymphosarcoma Recovery was interrupted by an abscess, after which it proceeded normally. Marconi, who reported the operation in the Italian "Clinica Chirurgica" of Dec. 31, 1893, qualified it as "the greatest operation ever done at any epoch or in any country." Illustrations of the tumor and adherent ring of vein accompany this article.

9. Treatment of Arteriosclerosis with Anorganic Serum.—The Journal has published accounts of the experience of various writers with Trunecek's "serum" from time to time He states now that the direct indications for it are permanent high pulse tension (without nephritis), dyspnea, cyanosis, angina pectoris, symptoms of arteriosclerosis of the brain and chronic alcohol intoxication. Besides these conditions, a favorable effect may be anticipated when, in addition to subjective symptoms of arteriosclerosis, the urine is very acid or contains a large amount of urates or calcium oxalate. Drinks and exercise should be avoided that tax the heart. The food should be selected with a view to facilitate oxidations and increase alkalinity, and taken in small amounts at a time. The serum reduces the arterial tension, and with this subside the subjective symptoms, the sounds in the ears, vertigo or polyuria It has proved a sovereign remedy for the dyspnea of arteriosclerosis, even in cases in which the symptoms had not been relieved by sedatives In severe cases the injections may have to be repeated every third day. The benefit is not always constant in angina pectoris, some cases proving rebellious, while others are quite cured by 15 to 20 injections, at intervals of four or five days In a case of aneurism of the right subclavian with compression of the brachial plexus, the dyspnea which occurred constantly on the slightest exertion was completely cured and the paresis of the right arm much improved. The patient felt quite well for fifteen months, when the arm involved became the seat of severe pains, which vanished after injection of 150 c c. of the serum. In a case of aneurism of the aorta the paresis of the recurrens was also partially relieved by the treatment, but the patient succumbed later. In various paretic conditions, especially those consecutive to apoplexy, even after they have lasted for months and years, striking and durable improvement may be attained by 8 to 10 injections of 3 to 5 c c. each, repeated at three to five day intervals. By the time 100 to 150 c c. have been injected the patient is usually completely cured. It is also effective in cases of chronic alcoholism free from gross lesions in kidneys or liver. Appetite and sleep return in arteriosclerotic cachexia, and the cyanosis is usually entirely banished by injection of 10 c c. of the serum. The composition of the serum was described in The Journal, xxxviii, p. 484. Trunecek thinks that its action is probably due in part to its binding a certain amount of the carbon dioxid in the blood. As much as 2 c c. are bound by the usual injection of 5 c c. of the serum. He finds it more difficult to explain why the function of the heart and paretic conditions are so much improved by even a small amount of the serum.

12. Formol-Phenol Treatment of Cancer and Lupus.—Ranelletti reports further experiences with his "mirmol," a combination of 10 per cent. formol with .3 per cent. phenol, for local application to malignant neoplasms and to lupus. The lesion is first cleansed with warm water to which 20 to 40 drops of formalin have been added per liter. After drying, it is swabbed with a solution of the mirmol, one part in nine parts warm water at first, gradually increasing to a 25 per cent. solution or using full strength, and an impermeable dressing applied. He describes 35 cases of malignant neoplasms treated on these principles and a few typical cases of lupus to portray the great benefit derived. The results of mirmol treatment are durable, he adds, and he recommends it for general adoption for cases in which surgical intervention is impracticable and in which the lesion can be conveniently bandaged. One of his lupus cases had resisted years of treatment of various kinds, including a course of tuberculin, the ulceration constantly discharging and the lesions spreading. Under mirmol the ulceration dried up and was substituted by cicatricial tissue, the large nodules became atrophied and the smaller disappeared entirely. The patient moved away from the city before treatment had been quite concluded, but the lupus had been reduced to a very few minute ulcers.

15. Prevention of Otitis in Measles.—Sugar has every child with measles treated when first seen by instillation of a few drops of a 5 per cent. solution of silver nitrate, dropped into the nose as the child lies on his back. Where this has been done as a routine prophylactic measure, otitis developed in only 4 out of the 60 children. On the other hand, in an experience of 111 children not thus treated otitis was observed in 18.

22. Subcutaneous Injection of Brain Emulsion in Traumatic Tetanus.—Krokiewicz brings up to 16 the number of cases, by reporting 3 personal and 1 from Gluzinski's practice. Three of the 16 terminated fatally and in 8 of the 13 recoveries the clinical course had been exceptionally severe. On account of the simplicity and harmlessness of the subcutaneous injection of brain emulsion he reiterates his former appeals to practitioners in general to resort at once to it in cases of tetanus. An emulsion of rabbit brains was used in the 4 cases that he reports. In one 6 injections were made in seven days, the emulsion containing the entire brain of a rabbit each time; in the others, 4 and 5 injections. Previous medicinal treatment had been entirely ineffectual. He thinks that the mortality would be materially reduced if the injections were undertaken earlier.

24 Local Treatment of Internal Affections.—Schuller had occasion to treat, in 1894, a woman with an abscess in the lung consecutive to grippal pneumonia. After evacuation of the abscess a chronic infiltration of the lobe of the lung persisted, inducing a kind of chronic hepatization, rendering the entrance of air impossible. After the failure of internal medication he injected into various portions of the infiltrated lung about 120 gm. of sterile saline solution. The benefit was evident in a few days. The cough diminished, the sputa became more fluid, the dulness retrogressed and the respiration improved. The saline solution had loosened up the masses accumulated in the alveoles and favored their expulsion in sputa or their absorption, allowing access to the air. The general health rapidly improved as the circulation in the lungs returned to normal. A year later there was no trace of dulness and respiration was full and deep.

28. **Etiology of Fecal Vomiting.**—The patient observed by Plesch had an incipient tuberculous affection in lung and in the intestines, with a history of well-treated syphilis a few years before. The *symptom of fecal vomiting* was observed for a year, but no sensitive point in the abdomen could be palpated, and no aggravation followed the commencement of the fecal vomiting. The autopsy showed a fistula between the stomach and transverse colon.

35. **Specific Albuminoids in Milk.**—The research described confirms the specific character of the constituents of the milk of various species and the importance of mother's milk for infants. A large proportion of the albumin in human milk is dissolved in the milk in the form of "laktalbumin," all ready to pass from the blood of the mother into the blood of the child through the milk, without requiring any chemical transformation. Cow's milk contains very little of this "laktalbumin," and it is altered by heat and requires some chemical transformation before it can be taken up by the infant's blood, in the meanwhile exerting a toxic action. The albumin of one species has an unmistakable *toxic action* on another species, until the system becomes accustomed to it, like alcohol and nicotin.

37. **Births After Symphysiotomy.**—Three women were delivered at Gessner's Maternity at Erlangen who had previously undergone symphysiotomy. One had borne five children since. In all the conditions were so improved by the symphysiotomy that subsequent births *proceeded normally* in every respect. Ihl has found only 84 births on record after symphysiotomy. In 50 the delivery was normal; in 24 a second symphysiotomy was required; in 4 version and extraction; in 5 artificial delivery, and in 1 perforation. There is no doubt that, with a child of ordinary size, the pelvis remains permanently enlarged after symphysiotomy.

39. **Treatment of Malignant Pustule.**—Federschmidt advocates immediate excision and reports 3 threatening cases in which *excision was followed by complete recovery in one to three days.* In 7 other cases in which treatment was medicinal or expectant, 2 deaths occurred.

41. **Diagnosis of Intestinal Occlusion.**—A young woman of 26, with hysteric antecedents, presented symptoms suggesting appendicitis with high fever, and the red, swollen appendix was resected. Some hard masses were palpated in the cecum at the time. The pains recurred and the temperature rose again and again to 40.5 C. At a second laparotomy the hard masses in the large intestine were then recognized as foreign *bodies adherent to the walls.* They were cautiously manipulated and massaged until detached from the walls and worked along towards the rectum. The abdomen was then sutured. Several hours later copious irrigation of the intestines resulted in the evacuation of ten linen rags, each 4 or 5 sq. cm. in size, and two more were voided a few days later after another brief elevation of temperature, which fell as soon as the rags were passed.

42. **Spontaneous Disintegration of Urinary Calculus.**—Görl was able to watch with the cystoscope the gradual crumbling of two stones in the bladder as the patient, an obese man, was put on an Ebstein diet and two quarts a day of a lithia water.

43. **Half Symphysiotomy.**—Diehl reports the successful delivery of a very small woman with a generally contracted pelvis, by slitting the upper half of the symphysis alone. This semi-symphysiotomy proved sufficient to allow delivery of the child, and the mother was able to be up in three weeks and *was soon at work as before, with no apparent trace* of the intervention.

44. **Prevention of Seasickness.**—Dornblüth points out that the disagreeable sensations of seasickness, riding in elevators, etc., are connected with the descending motion. He has found that if he takes a deep breath as the descending motion commences, the abdomen is distended and held firm by the diaphragm and no disagreeable sensation is experienced. The *measures that have been recommended against* seasickness accomplish the purpose as they comply with these conditions, immobilization of the abdomen during the descending motion. He believes that the resistance to seasickness can be enhanced by taking 2 or 3 gm. sodium bromid every evening for a week beforehand and during the trip, if a long one. He adds that it is very important to take regular meals at the accustomed hours, and that an abdominal bandage may well substitute the corset.

45. **Discovery of Anesthetic Action of Yohimbin.**—Loewy refers to Lewitt's article in the "Deutsche Med. Wochft.," 1902, Nos. 47-48, which presents all the facts and literature to date in regard to the efficacy of yohimbin in curing impotency. Magnani has recently discovered that the conjunctiva and *cornea lose all sensitiveness* for half an hour after instillation of a few drops of a .3 to 1 per cent. solution. The conjunctiva becomes hyperemic, but the pupil is not affected, in which

MEDICAL DISCOVERIES BY THE NON-MEDICAL.

GEORGE M. GOULD, M.D.
PHILADELPHIA.

I have been struck by the fact that the majority of great medical discoveries, truths and instruments, have not been made completely and suddenly, but have been led up to by preliminary and progressive steps, and that the layman has so often made these discoveries prior to the medical practitioner. This great medical truth is, indeed, but an illustration of the general law that all professional progress, in whatever branch of study, is somehow or other a result of stimulus from without. There is so much interest, and there are so many lessons to be drawn from such observations in medical history, that I have in late years kept minutes of this class of truths, from which I make the following selections:

When we commence observation of the origins of medical discovery and treatment, we are struck by the fact that "our brothers the animals" were first in learning not a little of medical art. It has been noticed[1] that birds often show a true surgical instinct. M. Tatio on several occasions has killed woodcock that were, when shot, convalescing from wounds previously received; and in every instance found the old injury neatly dressed with down, plucked from the stems of feathers, and skilfully arranged over the wound, evidently by the beak of the bird. In some instances a solid plaster was thus formed, and in others ligatures had been applied to wounded or broken limbs. Ten times in his experience he has found birds whose limbs had been broken by shot with the fractured ends neatly approximated and ligated together—a statement that is vouched for by no less a naturalist than Fulbert Dumonteil. Dr. James Weir[2] says that when bees are attacked with diarrhea they at once begin to suck astringent pieces of the dogwood, poplar, wild cherry, or hickory, and readily cure themselves. Their instinct carries them so far that "in winter if they should happen to be afflicted with diarrhea, they will readily drink a decoction of wild cherry if it is placed in the hive. Moreover, they seem to know that filth is a source of disease, for in winter all the sick members of the hive deposit their dejecta as far from the combs as possible. As soon as warm weather arrives, the accumulated filth is removed and the spot carefully cleansed." Dr. Weir further believes that many of the higher animals have discovered and use a materia medica that should be recognized by human physicians. For instance: Dogs will seek out and devour the long blades of couch-grass (*triticum repens*) when they are constipated; horses and mules will eat clay when they have "scours"; cattle with eczema have been seen to plaster hoof and joint with mud. He speaks of seeing a cow break thin ice on a pond and treat her itching joint to a mud poultice. Cats will go miles when they are "under the weather" for a dose of catnip. The saliva of animals seems to have a distinct curative action. Dogs, cats, cattle, rodents, monkeys—all lick their wounds when they can get at them, and soon effect cures. Weir also tells of a large dog-faced monkey who scratched his shoulder badly on a projecting nail in his cage. He immediately went to a corner and, seizing a handful of clean sawdust, pressed it on the bleeding scratch. In a few moments the bleeding ceased and the blood dried, leaving a coating under which the healing was prompt. Rev. Egerton R. Young,[3] a missionary in northwestern Canada, shows us that the surgical instincts of the dog may become so far developed as to produce a real surgeon-doctor. One of his dogs spontaneously took up this work, and became so expert that the Indians called him *Muskeke Atim*, the surgeon. Galls, wounds, frozen feet, etc., in the other dogs were successfully and systematically treated by Doctor "Rover." The wounds or sores that could not be reached by the dog's own tongue did not heal. The fact shows that, in a state of health and with pure food, the dog's saliva has a perfect bactericidal and healing power. Perhaps it would make an ideal antiseptic. No bacteriologist has caught the hint.

The logical or evolutional order of the subjects of my list would be to pass from the medicine of animals to that of savages, and so, finally, reach the more compact body of truth now held by the profession. I am compelled, however, to take the matter up topically, in order better to place it before you; the contributions of primitive men must, therefore, be noticed as we proceed from subject to subject.

In the history of medicine *ophthalmology* was one of the earliest subjects to command professional opinion. The eye is the most important of all the organs of sense, and blindness the greatest of afflictions. The early gatherings of medical lore, in large part, relate to the eye. The operation of *couching cataract* goes so far back in primitive times that Ælianus says that men learned it from goats, who, by pushing their heads against the thorns of a thorn-bush were accustomed to operate on their own cataractous eyes. It is noteworthy that in the operation by the Greeks a mydriatic was used and local anesthesia, as well as general narcosis, was induced.[4] The greatest discovery in this specialty is held to be the ophthalmoscope, but two others, in my estimation, far outrank it. Before Helmholtz, a non-medical man, Babbage, doubtless devised an strument "for the purpose of looking into the interior of the eye," and even Helmholtz said of himself that it was not inclination but external circumstances that forced him to become, temporarily, a physician.

According to Dr. John Green,[5] *spectacles,* both convex and concave, were in common use by the Chinese before the opening of commerce with Europe. They were made of a transparent stone, of a color like that of a strong infusion of tea, called scha-chi (tea-stone), and were tied on the head by silken cords. The common use of some form of magnifying glass by the ancients is well proved by their perfect workmanship, as displayed in the engraving of gems; and a crystal wrought in the form of a convex lens has been actually discovered in the ruins of Nineveh by Sir Francis Layard. Pliny's description of the visual defect of the Emperor Nero strongly suggests compound astigmatism. The statement that Nero was accustomed to view the conflicts in the arena by means of a smaragdus would seem to be best explained by assuming that the emperor possessed a large, highly-polished emerald, very likely of uneven curvature in its two principal diameters. The theory implies that the use of the gem for this purpose was the result of an observation made by Nero himself, who may, therefore, be credited with the accidental discovery of an eyeglass suited to myopia or compound myopic astigmatism; the invention apparently died with the inventor. Certain it is that spectacles were in common use for at least 150 years before the theory of their action was explained. Bifocal lenses were devised by a layman, Benjamin Franklin.

Although a physician discovered *astigmatism,* it was the mind of the natural philosopher or physicist in him that made the discovery, not that of the medical man. The discovery of the clinical significance of astigmatism was made by a physician, S. Weir Mitchell, 75 years later.

The laryngoscope is one of the best illustrations of a great medical discovery made by a non-medical man. The inventor of this instrument was a singing master of London, Señor Mañuel de Garcia, who was still living[6] in London in 1901, in his 98th year. In 1855 he presented a paper to the Royal Society of London, entitled "Physiologic Observations on the Human Voice." His investigations were carried out on himself by means of mirrors, a small one at the end of a long stem, for introducing into the pharynx, and a large one, which served both for directing the light on to the small mirror and to enable the operator to see the image formed on it. Garcia's invention was treated by the English with apathy and even incredulity. His paper, however, fell into the hands of Türck of Vienna, who failed with the device, but later, Czermak converted it from a "physiologic toy" into an instrument of scientific research and popularized its use by his demonstrations on his own throat in Vienna, London, and elsewhere.

In the seventeenth century Sir Kenelm Digby published his book on the cure of wounds by the "Powder of Sympathy." The knowledge of this wonderful powder, he says, came from a priest just returned from the Orient. By the aid of this "vitriol" he claimed to heal wounds without either touching or seeing the patient, by dissolving some of it in a vessel containing water, and putting in this water any article having on it blood from the wound to be treated. In the meantime the patient was advised "to cast away all plasters, only keep the wound clean and in moderate temper 'twixt heat and cold." However absurd this may seem, Draper tells us it was the beginning of the doctrine of *adhesion,* or the cure of wounds by immediate union, a practice little appreciated until the days of John Hunter; while Dr. W. A. Hammond claims that it embodied all there is of real value in our modern antiseptic treatment of wounds, and occasioned a greater revolution in the treatment of wounds than has been accomplished in later times by Lister and his followers.

I make the following excerpt from Baas[7]:

> *The first cesarean section* on the living and parturient woman was practiced by the sow-gelder, Jacob Nufer, of Siegershausen in Thurgau, on his own wife, about the year 1500. After 13 midwives and several lithotomists had endeavored in vain to relieve her, her husband, having invoked the assistance of God and obtained the special permission of the governor of Freuenfeld, operated "just as on a sow" with such good fortune that the mother survived to the age of 77, and was able subsequently to bear several children—and even twins—in the usual way. Undoubtedly, therefore, the operation was unnecessary, and the same was true of many of the operations which soon followed; for cesarean section became the fashion for a short time. A sow-gelder is said to have removed the ovaries of his own daughter in consequence of her lasciviousness, during the 16th century (Weyer tells the story), so that such fellows and operative gynecologists are to be considered the predecessors of Hegar, and to be praised accordingly.
>
> As a result of this enrichment of the technic of operative midwifery by a simple sow-gelder, the cesarean section seems in the course of the 16th century to have been practiced repeatedly, e. g., in Italy in 1540 by Christof. Bain; 1531, in Neusse; 1549, by Paul Dirlewang, on Marie Volcser, in Vienna, etc. Now, however, it was performed in a somewhat more becoming fashion, and chiefly by barbers, though some will admit as the first actual cesarean section only the one performed by Surgeon Trautmann in Wittenberg in 1610.

Celiotomy, according to Dr. Benjamin Howard,[8] was known by Japanese physicians of "centuries ago," one of whom wrote, "When medicines are ineffectual, as well as acupuncture, and the cautery, the abdomen and back may be opened, and the stomach and intestines washed."

According to Dr. W. J. Hoffman,[9] the Coyosteras Apaches employed a *splint in fractures* and gunshot injuries of the extremities that is well worth interest. An illustration is shown of an appliance used by a warrior for a comminuted fracture of the middle third of the left humerus. Strips of cedar wood, ¼ inch thick, ¾ inch wide, and 8 inches long, were bound together with sinew and applied to the arm by tying the loose ends of the sinews. Through the spaces between the strips water could be applied and a free discharge likewise secured.

Dr. McClanahan[10] says of the Indian *treatment of compound fractures:*

> First, reduction by extension and counterextension. Some of the medicine men acquire considerable skill in manipulation and their results are creditable. Next all the openings are filled with bone-marrow extracts. Then over all is smeared a coating of the scrapings of rawhide boiled in water. This forms a gelatinous layer having considerable strength. Over this and around the entire limb is placed a covering of fine inner bark, when the limb is ready for the splints. These go entirely around the limb, being held in place by circular strips of cloth. If it is an arm, this is carried across the chest and retained by a circular bandage about the neck.

Franklin Staples[11] states that the Talmud describes, among other operations, one for *stone in the bladder* and others for the reduction of various fractures and dislocations.

F. Poncet[12] pictures a terra cotta image found in Phœnicia, in which there is represented a perfect hernial bandage, with two metallic plates, to be fitted over the inguinal openings. It leaves practically no doubt that the Phœnicians recognized *hernia* and knew of its *successful mechanical treatment.*

According to the Talmud, *carbuncles* were manipulated with the fingers and then cut crosswise (crucial incision of to-day). In *atresia of the anus,* splitting of the skin down to the rectum is mentioned. (Sabb. 134, 1.)

The collections of surgical instruments made from the ruins of Herculaneum and Pompeii bear witness to a high degree of specialization and art on the part of the Roman surgeons of that time.

Wunderbar enumerates from the Mishna and the Talmud no less than 56 forms of surgical instruments and appliances, exclusive of the obstetric stool referred to in Exodus, 1:16.

Surgeon-Major William Curran[13] says:

> Narrating in a kind of autobiography the adventures of Captain Creighton (who fought under Montrose or Dundee in Scotland) and describing how Creighton had sustained wounds in a fight at Airs-Moss, Swift represents Creighton as speaking of his wounds as follows:[14] "My surgeon, having unfortunately neglected to tie a string to the tent of green cloth which he used for the wound, the tent slipped into my body, where it lay under my navel seven months and five days, and pained me exceedingly. The tent lying thus in my body made it impossible that the wound could heal. Wherefore I ordered some pipes to be made in a mould through which the thin corruption continually issuing out of the wound, might be conveyed as through a faucet. These pipes I cut shorter by degrees as I imagined the wound was healing from the bottom, till at last they became too short. Wherefore I made a coarse pipe myself which was long enough. This pipe, after the wound was dressed with brandy, was removed daily; and it happened one morning when the pipe was drawn out as usual, that the tent followed. Then I knew I should soon be well."

This Captain Creighton, in 1730-1735, was, therefore, the inventor of *drainage tubes.*

According to Dr. V. Deuffe, of the University of Ghent,[15] the rectal and vaginal speculum dates at least from 1000 B. C., a Sanscrit treatise by Sussutas (translated in 1844 by Hessler), describing such an instrument. It is also mentioned by Hippocrates and by other writers of the Alexandrian school, and has been found in the ruins of Pompeii.

In casting about for some means of combating mammary cancer, Beatson became interested in the custom prevalent among Australian farmers of *spaying cows* during lactation, in order to prolong indefinitely the period of lactation. It is during this period that there is enormous reproductive cell-activity with rapid destructive cell-metamorphosis. The cells involved in this process are of the identical epithelium, which undergoes hypertrophy in cancer of the breast, the difference being that in cancer continued growth of the epithelium takes place without any breaking down of tissue. The spaying results in cows, therefore, led him to try the same operation on women with *mammary cancer* in the hope that it would set up retrograde metamorphosis of the cancer cells. In several cases of inoperable cancer of the breast, he witnessed the disappearance of the tumor after *ovariotomy.* Abbe,[16] too, reports two remarkable cases in which ovariotomy was followed by rapid disappearance of recurrent cancer of the breast.

Anders[17], writing of the Winnebago and Dakota Indians, says that, as regards surgery, they never amputate. In large incised wounds, the parts are carefully brought together and secured with sutures of animal sinew, which they remove in 6 or 8 days.

As to *anesthesia,* Dioscorides[13] tells of a draught that may be given to human beings, before they undergo the pain of the surgeon's knife or cautery. Later, Pliny gives the formula of this draught, which was not only reputed to annul pain but was credited with producing a death-like sleep. Dioscorides further says, "a wine is prepared from the bark of the mandragora root, and three cyathi (a little more than four ounces) of this is given to those who require to be cut or cauterized, when, being thrown into deep sleep, they do not feel any pain." Pliny[18] remarks that the juice of the leaves of the mandragora is more powerful than the root. Of such a preparation he says the dose is six drams, to be taken before cuttings and puncturings. Speaking on the same subject, Apuleius[16] says that if any one is to have a limb mutilated, burnt, or sawn, he may drink a half ounce of the preparation, with wine, and while he sleeps the member may be cut off without pain or sense.

An editorial in *American Medicine,* April 19, 1902, says:

> From the fact that ancient anatomists referred to the carotid artery as *arteria soporifera* and that the Russians still call it *sonnaia* (the artery of sleep) it appears that it has long been known that, by compression of the carotids, a state of anesthesia may be produced. It is not surprising therefore to find that among the natives of Java, Madura, and Banku, a procedure for obtaining narcosis is in extensive use under the name of *tarik urat-tidor,* or compression of the soporific vessels. The anesthetizer sits in front of the patient and grasps the patient's neck with the fingers, the thumbs placed back of and a little below the angle of the lower jaw, compresses the internal carotid artery against the spinal column. Complete loss of sensibility and of consciousness is produced. L. Steiner,[19] of Saerabaya, Java, points out the absolute harmlessness of the method, the rapidity with which sleep may be obtained, and urges that it be given a place in surgery.

Benjamin Howard[20] says that "centuries ago" the Japanese used in celiotomies a narcotic mixture which contained *Datura alba,* aconite, etc.

In *gynecology and obstetrics* hardly a ray of scientific or rational light penetrated until modern times and civilization came to lighten the burdens borne by women of pain and superstition.[21] M. Weiss[22] says that the relation between *menstruation and ovulation* was known to the writers of the Talmud (vide Nida, 8, 1). Contrary to the Mosaic teaching, an intact or an injured hymen was not held as proof of either the chastity or the fall of a virgin; for it appears they recognized that conception was possible without the least injury to the hymen (Nida, 64, 2), while, on the other hand, mention is made of the fact that disease may give rise to destruction or atrophy of the hymen.

In *menorrhagia* astringent injections, such as the juice of strawberries and their leaves, or of plantain, was resorted to, reinforced by the use of pessaries of the leaves of plantain or knot-grass, bruised and rolled in a piece of fine linen, put "up in the womb."

Uterine prolapse was treated by reduction, followed by injections of the decoctions of galls; or, in bad cases, by the use of pessaries made of cork smeared over with wax, or sometimes made of wax alone. Fissured nipples were dressed with an ointment made of powdered elder bark, grease, and wax, i. e., an astringent.

In passing from surgery to medicine, we should note that the most ancient and persistent philosophy of disease, lasting down to our own times, was that it was due to some evil principle or spirit coming into the body from the outside, and to be fought against and driven out by any means possible and powerful. The germ theory, infection and parasitism, on which our science is now builded, shows how essentially true was the old perception.

For forty years I have been repeatedly struck by the fact that all *animals hate flies* with an intensity not entirely explained by their "suctorial," stinging, or biting powers. Our domestic animals, even our draught animals, expend as much energy in keeping off the pests as they do in our service, or in getting food. Even the most pachydermatous are not exceptions. If we observe an elephant, we are astonished at his constant watchfulness and exertions in keeping off the common flies whose suctorial powers are so feeble as to be entirely out of proportion to the energy spent by the elephant. Might not bacteriology have received a hint here of service in discovering the etiology of disease? Did not Nature long ago thus find out that flies might be the carriers of disease germs? Science is now rapidly advancing toward the same discovery. The entomologist of the United States Agricultural Department, Dr. Howard, after long studies, believes that flies are often the active agents in spreading typhoid fever. The bacillus of Eberth has been found in flies, and if Dr. Howard is right, then the profession must educate the public and nurses, and so order hospital construction and service that flies shall have no access to food.

In the Talmud (Ketuba 77:2) is mentioned a disease, "Rotz," characterized by weeping eyes and a discharge from the nose and mouth (influenza?) said to be communicated from man to man, sometimes by flies! The malady is plainly and unmistakably ascribed to an animal parasite.

In the light of the importance now being attached to flies as the carriers of contagion, much interest attaches to the fact that precautions against breeding grounds for flies about camps are to be found in the Scriptures. That grand old sanitarian, Moses, found it necessary to be most explicit in the management of camps. In Deuteronomy, 23: 12-14, the old version reads: "Thou shalt have a place also, without the camp, whither thou shalt go forth abroad. And thou shalt have a paddle upon the weapon; and it shall be when thou wilt ease thyself abroad, thou shalt dig therewith and cover that which cometh from thee." The new version reads: "Thou shalt have a paddle among thy weapons," and, as a variant for paddle, gives "shovel" in the margin. The passage, therefore, means that a shovel for burying excreta immediately is a necessary implement for the members of every camp.

> In a great empire[23] no question can be of more importance than the study of *malaria.* When we speak of one of our possessions as "unhealthy" it is in terms of "malaria" that we judge it. "Of all the diseases in our tropical possessions," says Dr. Willoughby Gardner in his interesting address to the British Medical Association, "by far the most important is malaria. It undermines the health of millions, and makes vast regions which would be otherwise our richest possessions, almost uninhabitable." In India alone, it kills every year some five million people—twice as many as cholera, smallpox, plague, and other infectious diseases put together. Indeed, one is almost tempted to agree with a writer in the Quarterly who says of the malarial germ "that it has played a greater part in human affairs than the greatest politician or general that ever lived." The first step in dealing with it was the discovery by the Romans, in the dawn of sanitation, that marshes and deficient drainage had much to do with its origin.

Herodotus writes (chapters 95-6) that the contrivances which the Egyptians use against the *gnats* wherewith the country (Egyptian marshlands) swarmed are the following: In the parts of Egypt above the marshes the inhabitants pass the night on lofty towers, which are of great service, as the gnats are unable to fly to any great height on account of the winds. In the marsh country, where there are no towers, each man possesses a net instead. By day, it serves him to catch fish, while at night he spreads it over the bed in which he is to rest and, creeping in, goes to sleep underneath.

A correspondent of the *British Medical Journal* (Aug. 30, 1902) writes that in 1864 one of her majesty's sloops anchored off Ajiabambo, in the Gulf of California, "dollar hunting," and sent boats ashore, the crews of which were to proceed a short distance inland to obtain the dollars which, in those days, the Mexican government did not allow to be exported. The medical officer seeing that the country was sandy and covered with brushwood, feared that malarial fever might result with the men so employed, but was assured by a resident that there were no *mosquitoes* and that "where they do not exist there was no chance of malarial fever." The officer reported this to the medical department of the navy, but it attracted no attention.

In the fifth century, B. C., Empedocles of Agrigento is said to have freed Selinante from fever by drainage of the stagnant waters about the city. A number of Roman writers are quoted by Marchiafava and Bignami,[24] showing that marsh lands were injurious to the health of man, because of the miasms, invisible animal and insect life, emanating from them. It was suggested that the mosquito was the origin of malaria as early as 1618. The Abyssinians[25] knew where and in what months malarial diseases are most prevalent and, by acting on this knowledge, they generally succeed in avoiding malaria. When absolutely obliged to cross such places as the valley of the Mareb in the fever season, they continually explode blank cartridges and light damp fires to keep away "the fever." The Chillooks and Bongos of the Upper Nile make great fires of dried cow-dung when their herds come in at night. Thus a cloud of smoke hovers over the village and protects men and beasts from the mosquitoes. The Andaman Islanders plaster their skins with a mixture of lard and clay to protect themselves from the bite of these insects. The scientific demonstrations of the relation between the mosquito and malaria is recent, but the natives of malarial districts suspected it long ago and protected themselves accordingly.

Alexander von Humboldt[26] says some of the Orinoco tribes of natives smear themselves with red paint, "to keep off the mosquitoes, probably."

A traveler through British Honduras relates[27] the following incident:

> One trifling incident will cause me to remember the negro colony at Tambol. In the Peten I saw a few cases of the disease called "pinta" which seems to be a dystrophy of the body pigment. It leaves the skin colorless or apparently white in blotches. Face, limbs, and body are liable to attack. Not only is it probably congenital, but it may be acquired by contact. On this particular evening the air was full of mosquitoes, and as we sat in the hut a man covered with the pinta blotches came to the door and would have entered, but the Carib woman drove him away, explaining her conduct by saying: "Signor, it is very bad that the mosquitoes that bite him should bite us. We catch pinta, tombière!" The mosquito is here re-

> garded as the disseminator of all manner of diseases, especially the pernicious fever of the tropical coast. So, the science of the natives is not so very far behind the times.

Indeed, the historic foreshadowings of the theory of the microbic origin of disease are too numerous to gather here. But more than to any other we owe to Pasteur the discovery of the microbic origin of contagious diseases—and Pasteur was not a medical man, not even a physiologist; he was simply a chemist. By his researches as to the origin of silk-worm disease, of charbon, or splenic fever, of chicken cholera, etc., he laid the foundations of preventive medicine, a branch of science which is, beyond question, the greatest benefactor of civilization.[28] His work on rabies must also not be forgotten.

The *Quarterly Review* of July, 1899, says that the prohibition of pork among the Israelites and Mohammedans probably arose from the danger of *Tænia solium* and *Trichina spiralis;* and the general use of hot drinks, like tea in China, was probably based on acquaintance with the ill effects that may result from the use of polluted water. . . .

And, as to *immunity,* natural and acquired, there have long been suggestions of the truth in the habits of animals, and in human life everywhere. Old citizens of rattlesnake countries know of dogs which are not only fearless but which find their chief pleasure in hunting these snakes. Having been bitten and escaped death after their first experience, they become thereby immune, and thereafter progressively so with each fight. It is strange no physician ever realized the significance of the fact.

S. Weir Mitchell[29] says that it was an astronomer (Galileo) who gave us the first rude *thermometer,* and it seems to have been another, Herman Kepler, who first and certainly before 1600, *counted the human pulse,* or, at least, left a record of having done this memorable thing. Does it not, Mitchell asks, seem incredible that of the numberless physicians who sat by bedsides, thoughtful, with fingers laid on that bounding artery, none should have had the idea of counting it?

It is strange that physicians should have waited until 1858 before seeing the use of the thermometer in medicine. In that year Wunderlich first described and urged its use, although the writings of Newton and Franklin show that it had been used long before for ascertaining the temperature of the human body. It was such a curiosity that one, about a foot long, is said to have been exhibited, less than 45 years ago, at a meeting of the British Medical Association by Sir Samuel Wilks, exciting curiosity and levity.

K. N. Macdonald[30] says: "*Inoculation with smallpox virus* has been practised by the Burmese from time immemorial. Among them, smallpox was called the inevitable disease, because of their idea that it is rooted in the human body from the time of birth. The usual procedure in inoculation is to mix the virus with milk and insert it under skin of the arm."

Immerman[31] claims that accounts of the inoculation of human smallpox may be found in the records of the most ancient times. Long before the beginning of our chronology, variola was purposely inoculated as a prophylactic measure in Hindoostan and China. In the latter country, the method never progressed beyond clothing the individual to be inoculated in a shirt impregnated with variolous pus or stuffing dried smallpox crusts into their noses. These measures frequently failed and they still more frequently led to violent variola. It is probably true, however, that in China the method never progressed further than this. In Hindoostan, on the other hand, the priests traversed the country in the spring of every year, and the virus was introduced by means of scarifications made on the outer surface of the arm or forearm, 15 or 16 in number, one-half inch long, and parallel. This area was then covered with a compress of cotton wool impregnated with the virus and moistened with the water of the Ganges. In addition to Hindoostan and China, with their primitive methods, it has been established that prophylactic inoculation was practiced by the inhabitants of Barbary and Senegal in Africa, and by the Circassians and Georgians in Asia before it crossed the Bosphorus.

Immerman[32] says that the fact that the so-called *vaccinia* (cowpox) was capable of transmission to the human individual has been known for an indeterminate period of time. Long before the days of Jenner it had been observed that individuals who had never had smallpox, but who had accidentally been infected with cowpox, remained immune when subsequently exposed to variola. Alexander von Humboldt, for example, says that since the earliest recollection of man, certain tribes of Indian shepherds in the Mexican Corderillas had been thoroughly convinced of the protective effect of vaccinia against variola. Brun makes a similar statement in reference to the clan of Elihats in Beluchistan. The belief in the immunizing effect of cowpox was also prevalent among the country and dairy folk of Europe and thoroughly rooted in certain parts. The tradition brought, by a dairy maid, under Jenner's notice, was widely spread in all the dairy districts of England and Ireland; it was prevalent in as many as 18 English countries.[33] Benjamin Jesty, a farmer of Dorsetshire, England, was probably the first person in Europe to *vaccinate with bovine virus for prophylactic purposes.*

The material relating to Jesty has been set forth by Crookshank in his work on the "History and Pathology of Vaccination," and it has been summarized by Dr. McCrae in the *Johns Hopkins Bulletin* for February, 1900, his article being illustrated by Say's engraving of Sharp's painting.

> Benjamin Jesty[34] was born at Yetminster in Dorset, and was a farmer who moved to the farm of Downshay in the Isle of Purbeck, near Swanage, in Dorsetshire. He appears to have been an eccentric man, full of quaint actions and speech, but with good power of observation and of sensible reflection on what he had observed. In 1774 smallpox was prevalent in his locality. He was thought to be in no danger of it himself, as he had already acquired cow-pox, which he had contracted accidentally from the cows. Some of his famly were not so protected, and the fact that two of his maidservants, who had previously had the disorder from the cows, attended patients suffering from smallpox without infection, seems to have determined Jesty to inoculate the cow-pox into his own family as a preventive of smallpox. Accordingly, Jesty carried out his ideas and inoculated his wife and two sons, aged 2 and 3 years, with the cow-pox. The patients went into the fields and the virus was taken on the spot from the teats of the cows. A stocking-needle was the *instrument used*, Mrs. Jesty being inoculated under the elbow, the sons above. The latter had the disorder in a favorable way, but in the course of a week Mrs. Jesty's arm was much inflamed. She had fever, and was so ill that a neighboring surgeon, Mr. Trowbridge, of Cerne, was called. He said: "You have done a bold thing, but I will get you through it if I can." She soon recovered perfectly, but the boldness and novelty of the attempt produced no slight alarm in the family and no small sensation in the neighborhood. Fifteen years later, in 1789, the sons were inoculated for the smallpox by Mr. Trowbridge along with others who had not had the cow-pox. The arms of the Jestys inflamed, but the inflammation soon subsided, and no fever or other variolous

symptoms were observed, while the unprotected individuals went through the usual course of inoculated smallpox. Subsequently Mrs. Jesty and her sons were often exposed to smallpox without taking it, while in 1805 one of the sons was again inoculated with a negative result. In 1805 the Jennerian Society persuaded Jesty to come to London for five days for the purpose "of taking your portrait as the earliest inoculator for cow-pock, at the expense of the institution; you will receive fifteen guineas for your expenses." He came and his portrait was duly taken, but he conceived a very unfavorable opinion of the metropolis, though he admitted it possessed one great merit, namely, that he could be shaved every day. He died April 16, 1816, at the age of 79, and he is buried in the little village churchyard at Worth Maetravers.

I can not forbear admitting that this magnificent act of Jesty has never been rated at its true value. That Jesty was a layman does not detract from the honor that is his due, but, to my mind, adds to it. Neither Jesty nor Jenner discovered the fact of immunity from vaccinia, and neither could explain it. That Jenner waited 25 or 30 years after the dairy folk had found the truth, and 22 years after Jesty vaccinated his family, before he vaccinated the Phipps boy, is not a reason for making Jenner the discoverer of vaccination. That honor seems to me to be due to Benjamin Jesty.

It appears[35] that the Chinese have long observed the association between the death of *rats* in the house and the appearance of a case of *plague* a few days later in the family living there. J. Campbell Gibson[36] directs attention to the fact that the disease which preyed on the Philistines, described in Samuel I, chapter v, vi, was bubonic plague, and that they recognized the dependence of the spread of this disease on rats (or mice as the text has it); the Philistines (who thought to appease Jehovah by sending back his ark) sent, at the same time, as guilt offerings, golden images of the tumors, the chief symptoms of the disease in those cases which were not fatal, along with golden images of mice. The importance they attached to this relation is plainly shown by referring to the Septuagint, wherein the tumors are spoken of as "plague boils," and it goes on to say "in the midst of the land thereof, mice were brought forth, and there was a great and deadly destruction in the city." The description of the disease is quite clearly that of bubonic plague; the recognition that mice were responsible is very interesting.

"Among the means of protection possessed by the living organism against infectious diseases and toxic agencies, laboratory investigation has placed the *bile;* but, as is true of so many other facts in medicine, empiric knowledge anticipated scientific discovery.[37]

It appears also that, from time immemorial, the peasants of central France have been in the habit of using the gall bladder as a remedy for viper bites. They seem to have anticipated the interesting and valuable experiment of Phisalix, Neufeld and Valée and others concerning the antitoxic properties of the hepatic substances. In the *Revue Scientifique* (Feb. 23, 1901) a correspondent adds this statement: "The natives of Bengal are not alone in knowing the antitoxic power of the liver and in employing it therapeutically. Although Professor Frazer of Edinburgh first showed by scientific experiment that the bile of the serpent is an antidote against the venom of that creature, the natives of Guiana[38] have, for years and years, treated poisonous bites with a powder composed of the liver and bile of the serpent. Moreover, in California, the Indians do the same thing.[39] And at our watering places to-day[40] one may see fishermen treat stings and pricks with a plaster of fish liver. It is interesting that such practices, scattered here and there, all over the globe, among the most diverse peoples, are not at all so irrational as might at first sight be thought. They are justified by the brilliant studies of Frazer on the action of the bile against venom, by those of Frantzius on the action of bile against the virus of rabies, and by those of Vicenzi on the action of bile against the virus of tetanus.

In *materia medica and therapeutics* our modern knowledge and methods of treatment are often accretions of the ages, and sometimes precisely those of the earliest times.

R. H. True[41] says that less than two dozen of the botanic drugs now in use, have been introduced during the century just closed. He defines "materia medica as that body of substances which, in the popular belief, possess efficacy as remedies, although no confirmation has been offered by science. Indeed, science has often merely put its official stamp on folk beliefs in producing our present materia medica." "The beginnings of our present materia medica antedate the most ancient papyrus or inscription. It seems to have had its beginning in Egypt, Phoenicia or India. There is even a hint of our modern hemotherapy, as arterial blood, dried and powdered, is sometimes used as a restorative."

The Talmud "pharmacopeia"[42] shows that there were used infusions, decoctions, draughts, wines, vinegars, syrups, liniments, cataplasms, blisters, ointments, electuaries, plasters, powders; also cathartics, emetics, tonics, sudorifics, expectorants, abortives, hemostatics, astringents, poultices. The following substances also receive individual mention: Wine, vinegar, honey, whey, cotton seed, walnut and olive oil, garlic, mustard, pepper, coriander, ginger; also ox-gall, calamus, aloes, myrrh, mint, cotton-plant, hyssop, thyme, broomtop, poppy, acacia, mandragora, mandrake, mush, mercury, soda, borax, alum, iron, copper, lead and yellow arsenic.

S. S. Cohen[43] observes that the use of *Passiflora incarnata* is not original with the medical profession, and goes on to say that Benjamin Rush told his students that they could learn many useful methods of treatment even from "quacks and old women." There is much that may be learned of drug-therapy from irregular practitioners whose crude reports of uncritical observations frequently contain accounts evidently truthful of trustworthy experience.

The use of *light as a curative agent* is said to have been discovered by accident and by laymen. In a communication to the Academie des Sciences, Dr. P. Garnault tells of his success in the use of light in the treatment of rheumatism and other diseases. His attention was first drawn to the subject by M. Trouve, who observed that a workman afflicted by rheumatism was completely cured by remaining in the vicinity of an intense arc-light used for an electric fountain, and, subsequently, that in works employing electric soldering, in which there is a great effulgence of light, workmen had ceased to be affected by such diseases as rheumatism and gout.

Another version is given by *The Practitioner* as to the light treatment of lupus:

> Four or five years ago (so runs the story) a watchmaker of Berlin was the subject of lupus of the face, for which he had been treated in the clinic of Professor von Leyden at the Charité Hospital. As the condition did not improve, the patient left the hospital and resumed work. He was in the habit of using lenses of high power. One day, whilst examining the inside of a watch, he was standing close to the window. The rays of the sun passed through the lens, the focus of which happened to be on a part of the man's face affected by the

disease. He felt a sharp pain, and on looking into a glass he saw that the burnt spot had become white. He repeated the experiment on the following days, keeping the lens sometimes for hours between the sun and the ulcerated places. In six weeks cicatrization had taken place, and the patient went to show himself to Professor von Leyden, who had declared that the disease was incurable.

"It is a fact that some of the greatest advances in medical treatment have been due to outsiders. But even if it be true that the watchmaker did discover for himself that lupus could be burnt with a lens, the fact can not detract in the least from the merit of Professor Finsen's achievement in working out the rationale of the process and the details of the method. The account of his experiments, given in his little book on 'Phototherapy,' which has been translated into English by Dr. Sequeria, of the London Hospital, is an admirable example of scientific method."

The writers of the Talmud[44] understood *massage with oil inunctions; diaphoresis* by means of warm baths; and, most noteworthy, *venesection* for plethora and quinsy! (See Joma, 84, 1.) The *therapy of water* was also crudely understood (Sabb. 78, 1). Even *hypnotism* was resorted to, but without any appreciation of its real nature. By laying on of hands, hysterics were cured of blindness, paralysis, hysteromania, and catalepsy (Joma 84, 1).

The routine treatment, says Anders, of *intermittent and remittent fevers* by the Winnebago and Dakota Indians is an emetic or cathartic, followed by a vapor bath in the sweat house and then a cold plunge. The after-treatment consists in a tonic made by decoction of the willow. In *rheumatism* they rely almost wholly on the vapor bath, also the black cohosh (*cimicifuga*) in decoction, treatment hard to improve on to-day.

For *mucous enteritis* and *dysentery* they rely entirely on decoction of buttonwood bark (or American sycamore), which Anders says is singularly effective in their hand. They also use *Geranium maculatum* (cranesbill) successfully in *diarrhea*.

H. M. McClanahan,[45] who lived among the Gros Ventres and Assiniboine Indians, says they have learned by observation that it is necessary that the skin, bowels and kidneys should perform their several duties. They induce perspiration most effectually by means of their sweat houses. These are about 4 feet high, 8 feet in diameter, and sunk one foot below the level of the ground. In the center of the dug-out, which is covered almost air-tight with blankets, are placed very hot stones, over which hot water is poured, and the occupants of the bath thus get a steam bath. (Observe how the Turkish bath is foreshadowed.) Then, unless it be freezing weather, the bathers go from the bath to the river and plunge in. To produce catharsis, they sometimes resort to abdominal kneading to excite peristalsis as we do to-day. In suppression of urine, small heated stones are placed under the patient's back, failing in which the steam bath is resorted to. Recognizing that an unarrested hemorrhage means death, they use compression and spider's web, the latter to favor clotting of the blood.

R. H. True[46] says that in the seventeenth century, the wife of the governor of one of the Spanish colonies (Peru), west of the Andes was attacked by malarial fever, and seemed likely to die. The natives gave to a Jesuit missionary, who worked among them, bark from a certain small tree, telling him to grind it up and give it to the countess at regular intervals. She recovered and, being of a philanthropic disposition, obtained a quantity of the powdered bark and sent it to Europe for use among the poor. In due time, the trees and plants were botanically investigated and named by Linnaeus, in honor of the house to which the countess belonged, "Cinchona."

The Aconitum[47] of the Greeks and Romans refers in all probability to the *Aconitum napellus*. The ancients were well aware of the poisonous properties of the aconites. It was used by the ancient Chinese[48] as an arrow poison, and is still in requisition among the less civilized of the hill tribes of India. Something of the kind was in vogue among the aborigines of ancient Gaul.[49] "The use of *buchu leaves*[50] was learned from the Hottentots by the colonists of the Cape of Good Hope." At a very ancient date *camphor* seems to have been a well-known medicine among the Chinese, and *menthol* among the Japanese.

Coca leaves[51] were cultivated by the Incas prior to the Spanish invasion for use on long journeys, to ward off fatigue. This fact drew the notice of Europeans and the discovery of coca and cocain resulted. W. G. Mortimer[52] states that there is a custom among the Peruvian natives of opening old graves for the purpose of recovering sacred relics. When these old graves are opened, although there is no apparent odor, those who explore them are very apt to get a sore throat from inhaling the vapors or impalpable powder into which the bodies fall as they are exposed to the air. It has long been a custom to fortify against this condition by the use of coca, thus illustrating the intuitive adaptation of a native remedy empirically which it has required long years of study to apply since in a scientific way in the treatment of throat troubles.

Zelia Nuttall[53] takes the following from an unpublished manuscript in the Royal Library at Madrid on the customs of the ancient Mexicans: "Inflammation of the gums is cured by lancing them with an obsidian knife and rubbing in a little salt with the finger. Or heat a red pepper or capsicum and press it along with a grain of salt as tightly as possible on the painful spot. If these remedies do not suffice, draw the tooth and put a little salt into the hollow place." It is certainly interesting to find, in ancient Mexico, the employment of the modern *capsicum* toothache plaster, and to realize that centuries of experience had taught the natives the value of capsicum as a counter-irritant and of salt as an antiseptic.

There is no doubt that the use of *collodion* as a flexible antiseptic dressing is foreshadowed in the way these same Mexicans burned wounds (cauterized them) and then covered them with the melted juice of the *ulli plant*—the india rubber plant. All this was prior to the Spanish Conquest.

Curare, under the various names of curara, woorara, wourali, etc., was used by the natives of Demarara and the valley of the Amazon to poison their arrows. T. L. Brunton[54] says that an animal wounded with one of these arrows soon lags behind the rest of the herd, and quietly dies without any sign of suffering, appears, indeed, to go quietly to sleep. After the animal was apparently dead, however, it was found by Europeans whose notice was drawn to the subject that the heart could be felt beating vigorously for a considerable time, and if an artery were cut across the blood was ejected forcibly from it. It therefore occurred to Sir B. Brodie in 1812 that if he could keep up the respiration until the poison was eliminated the animal could be saved. This was done, and a most valuable agent for physiologic experiment discovered.

The forerunner of *tannic and gallic acid* as applied to hemorrhages may be found, according to Dr. D. Mitchell,[55] in the use made of the decoction of oak-tree leaves in hemoptysis.

Jaborandi leaves,[56] collected in the Amazon Valley, first attracted the attention of explorers by its use in the hands of natives as a remedy for snake bite.

The *Kola nut* is made of much use by the African natives, who attribute to it divers medical properties. For instance, the nuts are used for their stimulant sialagogue and stomachic properties. The Africans[57] chew them, much as the Brazilians do coca; and ascribe to them quite as marvelous effects. These latter are found to be almost wholly due to the caffein which is present in the proportion of about 2 per cent.

A decoction of willow bark[58] was used by the American Apache Indians for intermittent fever. Our *salicin* is derived from this source to-day.

Strophanthus,[59] a remedy now widely used for heart troubles, was first brought to the notice of explorers of equatorial Africa as a very deadly arrow poison, so deadly as to paralyze the heart by means of the smallest wounds.

A. J. Currie says that Pliny (xxiv 9) gives numerous instances of the use of herbs by the ancient Celts,[60] e. g., hyssop for diseases of the eye. Broom-top, juniper and foxglove have long been known as remedies for dropsy, and, in suitable cases, with good results. For the cure of "white lights," an old Scottish name for pulmonary tuberculosis, nourishing food and fat substances were found to be of great vaue. *Oil from the blubber of the seal* was recommended.

About the time of Herodotus[61] the acquaintance of the lay people with simples appears to have been considerable; for example, the diuretic powers of *squill* in hydropsic complaints and the effects of the salts of *iron* on disorders arising from a want of proper tone in the system.

Dr. Justus Sinexon of Philadelphia (personal communication) in the forest of northwestern Maryland observed the guides eating *May apple* and chewing with it birch leaves to prevent griping. Dr. E. W. Kelsey of Philadelphia (personal communication) during his stay in the Klondike, found that the Alaskan natives used a decoction of *green fir boughs* as a remedy for scurvy.

In many instances the extraction of the essential principle of the plant which was first discovered by the nonmedical was made by chemists who were not physicians, and who derived their zeal for research from pure science rather than from therapeutics. This is especially true of the alkaloids, among which are atropin, brucin, cathartin, cinchonin, cystisin, delphin, digitalin, emetin, gentianin, lupulin, morphin, narcotin, picrotoxin, piperin, rhubarbarin, scillitin, solanin, strychnin, veratrin.[62]

E. T. Williams[63] states that, so far as we know, Moses was the creator of preventive medicine, an idea thought to be peculiarly modern. From whatever source the fragments of his system may have been derived the system was his own and that of the Powers which guided him. The notion of promoting health by preventing sickness was the foundation stone of the Jewish sanitary legislation. The prohibition against pork, considering the heat of the climate and its liability to be diseased, must be considered as a safe provision, especially in the light of present-day histology and trichinosis. The laws concerning "issues" or discharges from the genital organs, both of men and women, display similar wisdom. The laws concerning leprosy were strict. Every suspect had to present himself to the priest. If the diagnosis was doubtful, he was shut up for a week or two and then reexamined. Articles of clothing worn by lepers had also to be submitted. If found diseased they were burned. If doubtful they were washed and re-examined at the end of a week, when they were either burned or pronounced clean. When the walls of a house were attacked the affected parts had to be torn down and carried to a refuse heap outside the city. The remainder of the wall was thoroughly scraped, the scrapings themselves being carried out of the city and the broken places rebuilt with fresh materials. If these means proved insufficient the whole house was demolished and the debris removed from the town. Modern science may have discovered simpler methods of disinfection, but certainly nothing more thorough or effective. The object of circumcision is nowhere stated in the Bible. It probably does good by (1) reducing liability to venereal diseases; (2) as a preventive of masturbation; (3) by preventing phimosis and paraphimosis, and (4) it probably promotes continence by diminishing the pruriency of the sexual appetite.

Medicine, W. C. Bitting[64] says, never was a science among the Hebrews. Before the Exodus the hints of medicine are very scarce. For 430 years, however, the Hebrews were in bondage to the most enlightened people of the world. Herodotus (ii, 84) says of the Egyptian physician: "The medical practice was divided among them as follows: each physician was for one kind of sickness and no more; and all places are crowded with physicians, for there are physicians for the eyes, physicians for the head, physicians for the teeth, physicians for the stomach, physicians for internal diseases." Obstetrics among the early Hebrews was left entirely to the midwives (Genesis xxxv, 17). Ophthalmia with resulting blindness was not uncommon (Lev. xix, 4—Deut. xxvii, 18); leprosy was known in all its forms (Lev. xiv, 3—xxvii, 4—Numb. xii, 10, etc.); apoplexy cut down its victims (I Saml. xxv, 37); consumption thrust its ghastly symptoms into family life (Lev. xxvi, 16—Deut. xxviii, 22—Is. x, 16); rheumatism and gout twisted the joints of high livers and perplexed men as much then as to-day (II Chron. xvi, 12—Jno. v, 2, 3); epilepsy threw men into foaming fits (M. R. xix, 17—Luke ix, 38); atrophy of limb produced deformity (I Kings xiii, 4-6—Matthew xii, 10-13). In the matter of treatment, the materia medica was scanty. Balsam (Jer. viii, 22—xlvi, 11) was a favorite drug for external application, probably effective because it was a terebinthinate and therefore antiseptic. Wine because of its alcohol was also an antiseptic.

Purging was in vogue (Prov. xx, 30). Music was used to quiet Saul in his spells of acute mania (Sam. xvi, 16), which is quite in advance of many of our methods of to-day.

Moses[65] seems to have had great knowledge of medicine. In the book of Leviticus (xiii, 3-20) we find his three cardinal principles which to-day are utilized in the management of contagious diseases, namely, differentiation, isolation and disinfection. In Leviticus iv to xxvi one can not but be struck with the directions for preserving individual and public health; the selection of portions of creatures for sacrifice and rejection of those parts of the economy whose functions are the removal of impurities or excretions; the disposal of filth in such manner that it might contaminate neither air nor water; the disposal of the dead; disinfection and purification of clothing and dwellings, and the laws of quarantine.

In hygiene, says Bitting,[66] the Mosaic medicine is supreme. The priests were skilled in preventive medicine.

It was their duty to inspect and enforce sanitary arrangements. The history of the Hebrew race is singularly free from epidemics. Diet was carefully regulated. Pork was forbidden. To eat blood was a crime. Everything had to be washed before being cooked (Mark vii, 4—Lev. i, 9). Bathing was compulsory on those who had touched a leper, or those with any issue or flux (gonorrhea) or who touched anything that the diseased had touched (Lev. xv, 1-13), all men and women after copulation, women after menstruation—indeed, they ought to have been the cleanest people on earth. No doubt their freedom from venereal disease was due to these precautions added to the cardinal one of circumcision.

The sick were isolated as far as possible (Lev. xiv, 33-45). The lepers were kept outside camps and cities and away from the highways (Lev. xiii, 45, 46); the house in which leprosy originated was entirely demolished (Lev. xiv, 33-45); a little loss of real estate was cheerfully suffered rather than endanger the public health.

The camp sanitary regulations were the very best. Every man was his own scavenger. All refuse from the slaughter of animals was burned outside the camp (Ex. xxix, 14—Lev. iv, 11—viii, 17). Even the very spoils of war as well as the soldiers were to be disinfected before entering the camp after battle (Numbers xxxi. 21-24). What was not inflammable must be bathed in fire to cleanse it and everything else had to be washed in water.

From the Mishna (or Jewish traditions)[67] we learn how carefully all unclean things were removed from the vicinity of Jerusalem and the temple; and the investigations of Signor Perotti in that ancient city have revealed how complete were the systems of sewers and the means of sewage precipitation and disposal.

The Egyptians, says Herodotus (Vol. ii, Chap. 42), were particular in preventing anything remaining above ground which by putrefaction could taint the air; and this was the reason of their obliging every town to embalm whatever died there. . . . . To pollute the Nile with dead carcasses would have been in the highest degree inconsistent in a people so particular on this point. The Persians, Herodotus tells us (Vol. i, Chapter 139), never defile a river with the excretions of their bodies, nor even wash their hands in one; nor will they allow others to do so, as they have great reverence for rivers.

Herodotus tells us (Chapter 188, Vol. 1):

> The great king, Cyrus, when he goes to the wars is always supplied with provisions carefully prepared at home; and with cattle of his own. Water, too, from the river Choaspes (the modern River Kerkhah) is taken with him for drink. Wherever he travels he is attended by a large number of 4-wheeled cars, drawn by mules, in which the Choaspes water, *ready boiled for use and stored in flagons of silver* is moved with him from place to place.

The Greeks were evidently familiar with the purifying nature of *sulphur*, for Homer makes Ulysses say:[68] "Bring me, old woman, sulfur—the remedy for impurities—and bring me fire that I may fumigate the palace."

From all of these instances, and more that might easily be added, it would at first seem as if the discovery of new medical truth were almost hopeless. So much of our new knowledge is old, so much not true, that the common practitioner feels discouraged in any attempt to make additions to the existing body of truth. But to me, the lessons of these things cited are most encouraging, and should inspire the simplest mind with hope.

1. The plainest moral to be deduced is that a large deal of the ancient wisdom is really wisdom. It has been an egotistic habit to republish the nonsense and quackeries and superstitions of medical history as conceited proofs of how superior we are to our forbears. This was as foolish as it was untrue. We are not so mightily superior as we think. When we are really so we shall not boast nearly so much. Neither have we by any means learned all that the ancients and barbarians have to teach us. Modern armies and cities could still learn a great deal from Moses, one of the greatest men, and certainly the very greatest sanitarian of all history. And just at the present time one can not help feeling that the old, unused truth is often of more importance than the new one. The death rate is twice as high as it would be if we should give society the benefit of the medical truths discovered long ago, but which in our rage and race for new discoveries we have disregarded. We most urgently need the rediscovery and the practical use of the old truths. My own specialty, ophthalmology, has literally gone to seed, especially in the old countries; and there is no new discovery in any department of medicine of late years that will to a small degree lessen human suffering as would a rediscovery of astigmatism and a practical utilization of its relief.

2. It is remarkable that savages and barbarians have learned so many great medical truths and are so successful in the treatment of their diseases. With all their neglect, superstition, ignorance and crudity they have managed to get hold of many important verities, especially in things that do not appear on the surface of their lives, and are not observed by the superficial traveler. If our explorers were only medical men, or even if they were alive to the great need of accuracy and thoroughness in reporting facts of medical and hygienic value, we would learn much more than we have from them.

3. We are also incited by our illustrations to a more keen observation of the common people about us, even of old women and quacks. Even these have their uses, and are not altogether without perception of medical facts. No less a person than Professor James of Harvard College (and he was educated as a physician) opposed the passage of a medical practice act in Massachusetts, because he thought it might prevent the discovery of new medical truths by the people. I think he was ludicrously stupid, but he does not think so. There is nowadays little danger of the loss of new truth by the elevation of the educational standards of the medical profession. Genuine education teaches us that undiscovered truth lies all about us, and that the lowliest may not be scorned. Every eager and genuine student must necessarily be a discoverer. No disease has been exhausted. It still has secrets, and we should not fear the silly sneers of the over-self-satisfied, who rail at empiricism, for empiricism has given us our most valuable discoveries in medicine.

4. And the method by which we are able to make these discoveries is by careful and accurate observation. We must, in a way, exemplify in medicine the method of Sherlock Holmes, or better, of Zadig, as deduced from Voltaire's story by Huxley. We are prone to leave this method to the professional scientists and discoverers—and even, alas, to the quacks and scamps.

The striking lesson also appears that only by the unifying and systematizing power of modern science do the single and scattered discoveries of the world become of use to all. In all the instances cited it will be noted that prior to the rise of modern science no one people had the benefits of the discoveries made by others. Each was held in the bondage of medical barbarism, because whatever single or discrete truths were known the great mass of truths were not known, and so there was no grand or general progress. By taking all that was good in all parts of the world and systematizing them to a common beneficence our science has at a stroke already largely lifted the world out of its course of disease and is every day lowering the death rate, which is, as it were, the thermometer of social welfare, more and more rapidly.

"One of the greatest losses in medicine," says T. Lauder Brunton,[69] "is the loss of individual experience. Men, most able and successful in the practice of their profession, die and carry their knowledge away with them. Some men record the cases they have seen, but comparatively few are able to record their experience in such a way as to make it thoroughly available for others. Science takes each contribution and gives it to all." An admirable example, further continues Brunton, of the application to medicine of the method of "tracking" (method of Zadig) used to be told by Dr. Milner Fothergill:

> A surgeon, Mr. X., wishing to see the working methods of a celebrated quack, desired of the latter to be present some day at his office. The quack, much flattered that so great a man should patronize him, readily acceded to his request. Shortly after Mr. X. had taken his seat, a woman came in with a bottle of urine which she handed the quack. He looked at her, then at the bottle, held it up between him and the light, shook it and said: "Your husband's?" "Yes, sir." "He is a good deal older than you." "Yes, sir." "He is a tailor." "Yes, sir." "He lives at Scarcroft." "Yes, sir." "His bowels are obstinate." "Yes, sir." "Here," handing her a box of pills, "tell him to take one of these every night for a week, and a big drink of cold water every morning, and he will soon be all right."
>
> No sooner had the woman gone out, than Mr. X. turned to the quack, curious to know how he had made out all this. "Well, you see, she was a *young* woman, and looked well and strong; so I guessed the water was not hers. As I saw she had a wedding ring on her finger, I knew she was married, and I thought the chances were it was her husband's water. If he had been the same age as she was, it was hardly likely he would have any illness, so I guessed he was older. I knew he was a tailor because the bottle was not stopped with a cork but with a bit of paper rolled up and tied around with thread in a way no one but a tailor could have done it. Tailors get no exercise, and are therefore apt to be constipated. I was quite sure he would be no exception to the rule, so I gave him 'opening pills.'" "But how did you know she came from Scarcroft?" "Oh, Mr. X., have you lived so long in Leeds, and don't know the color of Scarcroft clay? It was the first thing I saw on her boots when she came in!"

5. And it is not only the intellectual, the learned, the laboratory worker who can discover the new or rediscover the old. There is even more chance for the busy daily practitioner if he will only keep his eyes wide open and not be swayed by custom and fashion from seeing the hitherto neglected, and from ferreting out its ignored or unsuspected significance. The method of Zadig is at the disposal of the plainest country physician. He sees or may see the facts at first hand which the laboratory physician too often is prevented from actually seeing at all. And there is a perfect reason why to the end of time the individual discoverer can never have his opportunity taken from him. It is because every organism, every patient, differs from every other in the world. The protoplasm of everyone's body differs in chemical construction from that of every other. Each master's footstep is known by his dog, its scent being different from that of every other footstep in the world. Albumin has never been correctly analyzed, never analyzed twice alike. Each patient's disease is therefore peculiar and individual. Our large classes of disease are only rough generalizations, as each nation and race will have its typical protoplasm; thus all true discoveries and treatments must be individual, and the *science* of medicine can never conquer or render negligible the *art* of medicine. When our therapeutics becomes absolute and certain each patient must be treated differently. All the general truths and theory can never discover all the truth of the individual case.

6. And not only may we in our pride unsafely ignore the lay-world, far removed in time, space or culture; we are just as wrong-headed if we think there is not a subtle and even splendid medical wisdom in physiology and pathology, in the mechanism's adaptations, the healing powers and the teleologies of the tissues and organs of all living bodies. The number of articles of our materia medica derived from the animal body is so great that I can not even enumerate them here. Much of modern medical laboratory science is an attempt to rediscover the methods Nature has taken to prevent or cure disease by secretions and devices whose intricacy and ingenuity astonish us. The advance of serum therapeutics and the use of the extracts of the ductless glands are instances.

Immunity, as we have seen, is a device of Nature. We are really only now relearning its laws and taking advantage of them. Disease in the making is often discoverable in the study of habits, for we know, although we are too prone to forget it, that function always precedes structure, and that therefore malfunction always precedes organic disease. It is a truism that every device of civilization has been previously invented and used by what in our materialistic day we are foolishly likely to call "unconscious" nature.

Viewed simply as a machine for the utilization of force, every animal body is vastly superior to man's most perfect engine. In the steam boiler and engine from one-quarter to three-quarters of the heat is wasted, and in our fireplaces and stoves about 90 per cent. In our lamps but a small fraction of the energy goes to the making of light. If we could make light as inexpensively as the glow-worm and fire-fly! If our electric machines were one-tenth as perfect as that of the electric eel!

And if this is true to the physicist, how much truer is it to the physiologist, the physician and the pathologist! The Deity of biology and of therapeutics long ago discovered the methods of cure and of the prevention of disease which we are slow in working out with our most advanced science. He calls each of us to be His co-worker!

28. There was a play published in 1768, called "The Devil on Two Sticks," by Samuel Foote. In it the President of the College of Physicians is represented as delivering a lecture. He says:

"Brethren and Students—I am going to open to you some notable discoveries I have made respecting the source or primary cause of all distempers incidental to the human machine; and these, brethren, I attribute to certain animalcule, or piscatory entities, that insinuate themselves through the pores into the blood, and in that fluid sport, toss, and tumble about like mackerel or codfish in the great deep; and to convince you that this is not a mere *gratis dictum*, an hypothesis only, I will give you demonstrative proof. Bring hither the microscope! . . . Take a peep. . . . Those two yellow drops were drawn from a subject afflicted with the jaundice— What d'ye see?

Last.—Some little creatures like yellow flies that are hopping and skipping about.

Hel.—Right. Those yellow flies give the tinge to the skin, and undoubtedly cause the disease; and now for the cure! I administer to every patient the two-and-fiftieth part of a scruple of the ovaria or eggs of the spider; these are thrown by the digestive powers into the secretory, there separated from the alimentary, and then precipitated into the circulatory, where finding a proper nidus or nest, they quit their torpid state and vivify, and upon vivification, discerning the flies, their natural food, they immediately fall foul of them, extirpate the race out of the blood, and restore the patient to health.

37. The following letter of a traveler in Bengal (Revue Scientifique, February, 1901, reprinted from Gazette hebdomadaire de Med.) is of interest. He says: "Three months ago a mad dog bit six or seven men, among them two of my bearers, wounding them badly. I at once had some iron heated white hot to cauterize the wounds. But the natives looked on laughingly. 'El Sahib' said they, 'it's nothing at all; we have an excellent remedy; you shall see.' The dog ran again. One of the men seized a stick and killed him; another ripped open the abdomen, took out the palpitating liver, cut some pieces off and gave them to each of the wounded men, who swallowed them, raw and bloody as they were. 'The danger is over now,' they said. As I was incredulous they brought me a young man on whose legs were large scars. Bitten by a mad dog some five years before, this man had eaten a piece of the animal's liver and had felt no evil effects from his wound.

The case I witnessed happened in March. It is now the 3rd day of July. The wounds have healed and the men continue in good health. The natives even go so far as to maintain that if this remedy be given to a man already stricken with hydrophobia, it will infallibly cure!

THE SINGLE CUFF METHOD OF CIRCULAR ENTERORRHAPHY:

A NEW METHOD.*

O. BEVERLY CAMPBELL, A.M., M.D.
ST. JOSEPH, MO.

A NEW METHOD.

A consideration of the evolution in the methods of circular enterorrhaphy occurring in the past seven centuries, with the use of mechanical devices and sutures, and by the suture methods alone, is indeed interesting.

The goose's trachea of the four masters, wood canula, dried intestine, Scarpa's tallow candles, Watson's gelatin tubes, Chopart and Sabatier's prepared cardboard, later, Senn's bone plates, Paul's bone tube, Ashton's rubber rings, Murphy's button, Jessett's bone tubes, Brokaw's segmented rubber rings, the potato cylinder, the forceps of Laplace and others, the rubber bulbs of Treves, represent the progress in mechanical devices; while the Glover suture and the open treatment of the wound, Jober's method, the Lembert suture, the Czerny-Lembert, the Maunsell method, Chaput's method, the Harris method, Kummer's method and the Connell suture, represent the progress in suture methods.

Considering the multiplicity of methods now in use, by mechanical devices and by suture, leads one to conclude that circular enterorrhaphy is still in an evolutionary state, that an ideal method had not as yet been devised.

Since Richat, Richerand and Treves, in the early part of the nineteenth century, taught that union is more readily obtained between serous surfaces than between mucous surfaces or beween serous and mucous surfaces, nearly all of the methods that have since been originated have adhered to the principle of obtaining union of serosa to serosa. The Lembert suture, placed through serosa, muscularis and submucosa with the knot outside of the lumen of the bowel, is probably the most universally popular method of suturing. Yet it must be admitted that closely placed sutures of this character in pathologic states of the bowel are often defective, because of pressure necrosis. The method is slow of accomplishment, also requiring great skill in placing the sutures through the submucosa without penetrating the mucosa. Should the mucosa be penetrated, a new danger is added, that of capillary oozing. By this method a diaphragm is formed within the lumen of the bowel, lessening to some extent its caliber. All of the methods in vogue which adhere to this principle produce a diaphragm within the lumen of the bowel, and some of the late methods have added to the danger of pressure necrosis, and have contributed a new danger in placing a foreign body within the lumen of the bowel, an occasional source of secondary leakage from necrosis, ileus, perforation and peritonitis.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

Some of these later methods, however, possess the great merit of being time-saving measures, which must be recognized as extremely important in cases demanding resection of the intestine. Chaput, in 1889, developed an operation termed circular enterorrhaphy by abrasion and application, in which he coapts denuded mucous surfaces, demonstrating that permanent union may be thus obtained. Robinson, in 1891, in a paper entitled "Circular Enterorrhaphy by a New Method," demonstrated union between serosa and denuded mucous membrane. Robinson's method, as well as Chaput's, does not produce a diaphragm within the lumen of the bowel. Harris, in 1892, presented a method involving the same principles as Robinson's method, with, however, an improved technic, in that he does not use a foreign body within the lumen of the bowel. Harris has also, besides extensive experiments on the dog, applied his method to the human intestine, demonstrating sero-fibrinous union. The requirements to be met in an ideal method are:

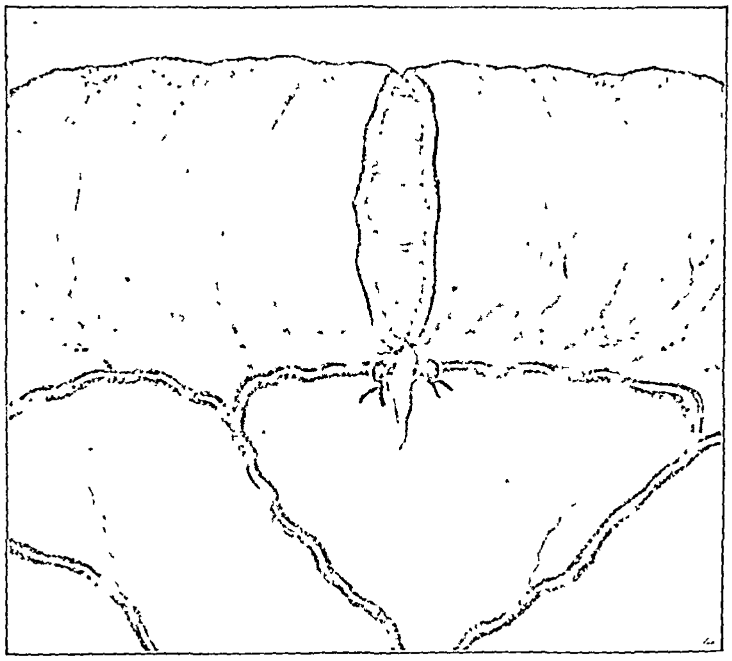

Fig. 1.—The mesenteric arteries are ligated, and a knife is passed through the mesentery and made to encircle the bowel, cutting through serosa and muscularis.

1. The union of the severed ends of the intestine by a method which provides against immediate and secondary leakage from the intestine.
2. The method must be applicable to pathologic conditions, as well as to the normal intestine.
3. Lessening of the caliber of the bowel at the site of union should be obviated.
4. Rapidity of execution.

I wish to present a method which, in my opinion, meets all of these requirements. The character of union obtained is serofibrinous.

DESCRIPTION OF METHOD.

The intestine is drawn out through the abdominal incision and its course determined. The contents of the intestine are stripped downwards and tapes or clamps applied. The mesenteric arteries are ligated. A knife is passed through the mesentery and made to encircle the bowel, cutting through serosa and muscularis. A cuff of serosa and muscularis five centimeters in length with the mesentery, is rolled back by means of gauze dissection on the distal portion of the bowel, which is well protected with gauze. The bowel thus denuded is severed at its distal end within one centimeter of the cuff. At the proximal end it is severed flush with the primary incision. Eight through-and-through sutures, the knots placed within the lumen of the bowel, unite the proximal end of the bowel to the denuded stump at the distal end.

The cuff is now rolled over the site of union on to the proximal end of the bowel and made secure by a suture placed through the mesentery close to the bowel and three interrupted sutures placed in the cuff through serosa and muscularis of the underlying bowel.

PRINCIPLES INVOLVED IN THE METHOD.

The cuff completely covers the sutures placed through the proximal end of the intestine and the stump of the distal end, so that leakage can not occur, as plastic lymph and blood agglutinate the cuff to the serosa of the proximal end of the intestine.

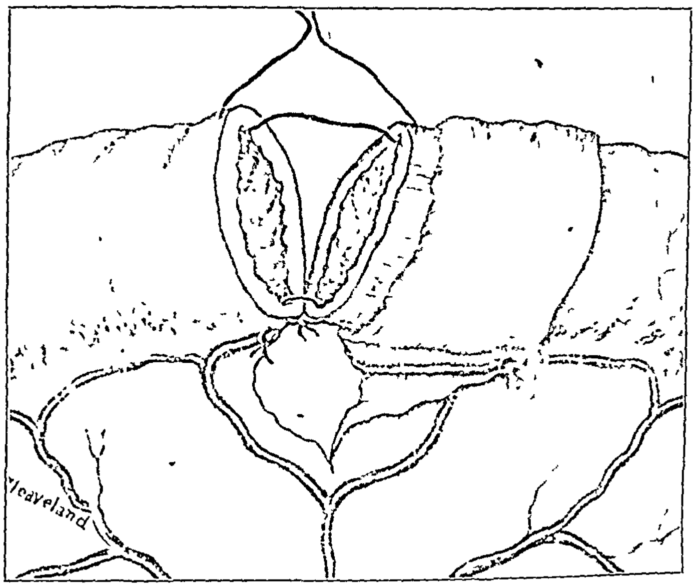

Fig. 2.—A cuff of serosa and muscularis with the mesentery is rolled back on the distal end of the bowel, by means of gauze dissection. The denuded area is severed at the distal end within one centimeter of the cuff, at the proximal end flush with the primary incision.

There can be no increase of tension on the sutures placed through the proximal end of the intestine and the stump, on the resumption of peristalsis, because of the rapid union between the cuff and the serosa of the proximal end of the intestine. The caliber of the lumen of the bowel at the point of union is unchanged.

ARGUMENTS IN FAVOR OF THE METHOD.

1. It is practical, easy of accomplishment and quick of execution.
2. It is the most natural way of uniting the severed ends of the intestine.
3. The cuff so covers and protects the sutures placed through the proximal end of the intestine and the stump of the distal end that the direct line of leakage and infection is obviated.
4. Pressure necrosis and leakage is not probable, and union is quite certain, as the blood supply to the cuff and the proximal end of the bowel that is covered with the cuff is undisturbed.

5. It is the most rapid of all methods, requiring but from five to eight minutes for its complete accomplishment.

6. It is the least complicated of any of the different methods now in use, and it can be safely performed by the ordinary surgeon, who rarely is called on to resect an intestine, quite as well as one greatly skilled in intestinal surgery.

7. Convalescence is more rapid and fewer post-operative sequelæ are likely to occur.

8. It is applicable to any part of the intestinal tract.

9. The security against primary and secondary leakage, furnished by the cuff, makes it the safest of all methods.

RESULTS OF EXPERIMENTS ON DOGS.

I will now submit a report of the pathologic findings following operation in specimens of union secured from dogs. There were four specimens examined, viz., two days, four days, eight days and thirty days, following the primary operations. The following is a report from the Columbus Memorial Laboratory, Chicago, by Prof. W. A. Evans:

Specimen 1 (The two days' specimen).—This is a piece of small intestine, with mesentery *attached.* It is 5¼ cm. long. Near the center of the specimen is a discolored area 2¾ cm. long. Four circular incisions were made, one just above the discolored area, two through it and one just below it. A circular piece showing the convexity *of* the bowel was removed *from* just about the middle of the discolored area. At this point there is about ½ centimeter between the outer and the inner circular muscle coats. A *second* longitudinal section was taken through the line of juncture between the red and white at its proximal end.

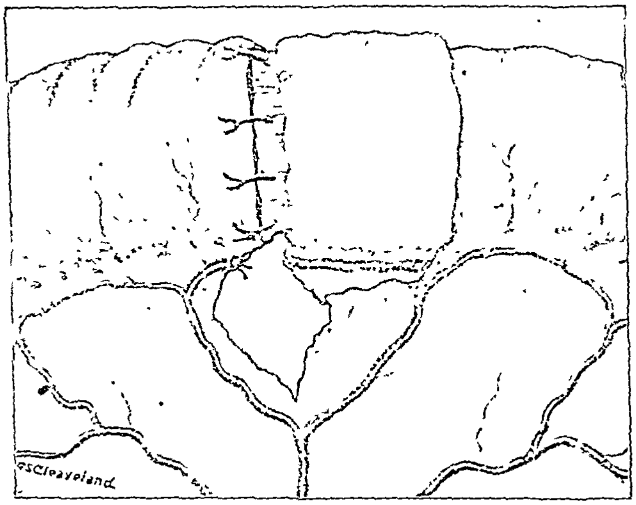

Fig 3.—Eight through-and-through sutures are placed through the proximal end of the bowel and the denuded stump of the distal end

Section A.—This is through the farther end of the cuff. Our sections are made lengthwise of the intestines. By microscopic examination we find the following: The mucous coat shows villi glands and other mucosa structures normal in every particular The muscularis mucosa is normal. The submucosa is normal It is rather thick just at the point of examination. This coat is quite thick, owing to it being the seat of a mucous fold. The circular muscle coat shows slight *infiltration* with leucocytes. The longitudinal muscle shows the same as the circular. Outside of the longitudinal muscle is a thin zone of mixed connective tissue fibers, *fibrin,* red *and* white blood cells. It is the union between the inner muscle tunic of the cuff and the serosa. It is as firm as it should be. This layer is about 1/10 as thick as the longitudinal muscle. Cuff circular coat is somewhat more inflamed than is the inner. Cuff longitudinal coat is somewhat more inflamed than the inner longitudinal. Cuff serosa does not show very well in sections.

Conclusions.—Union is good between the cuff and the underlying intestinal wall.

Section B.—This is a section made *from* near where the mucosa and the submucosa of one side was stitched to the wall of the other side. Mucosa: This coat shows villi glands and other mucosa structures. It is quite normal. At four points just on the mucosa side of the muscularis mucosa there is a moderate inflammatory reaction around the thread fibers. There are some leucocytes among those fibers. The muscularis mucosa is in two coats. In the submucosa there is moderate *inflammatory* reaction, especially along the vessel radicles. One thread is partly in this coat and partly in the mucosa.

Inner Circular Muscle.—This muscle shows one thread *puncture just about its juncture* with the *longitudinal muscle.* This layer shows a fair amount of inflammatory reaction along the vessel radicles.

Longitudinal Muscle.—This shows about the same amount of *inflammatory reaction as the circular coat.* Outside the longitudinal muscle is the layer of fibrinous adhesions. This layer is four millimeters thick as it appears on the slide. It is composed of fibrin infiltrated with leucocytes and *larger cells* with considerable perinuclear protoplasm. In this district the thread shows at several places.

Cuff.—Circular muscle fibers show considerable inflam*matory* reaction and extravasation of blood. The cuff longitudinal muscle shows *much* extravasation of blood and a fair amount of inflammatory reaction. The serosa, except for extravasated blood, is negative.

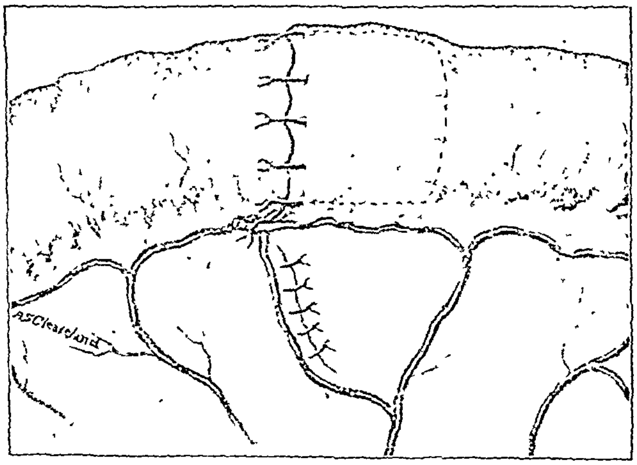

Fig 4.—The cuff is now rolled over the site of union on to the proximal end of the bowel. A suture is placed through both folds of the mesentery of the cuff close to the bowel above the anastomosing branch of the mesenteric artery, and through both folds of the mesentery of the proximal end of the bowel *Three interrupted* sutures are placed through the cuff into the serosa of the proximal bowel.

Specimen 2.—This is a piece of small intestine with partial mesentery attached. It is 8 cm. long. Length of the discolored area in this specimen is 2 cm. The incisions were made just above the discolored area, 4, 10 cm. below its upper border, 1 cm. lower down, and three other incisions *each 5/10 centimeters* apart.

Section A.—This extends longitudinally through the intestine at the tip of the cuff. The sections here show the same as in the section *marked* "Section A, Specimen 1." The photograph shows a very good union, still fibrinous, between the cuff and the underlying intestine. The other layers are about as reported in Specimen 1.

Section B.—This is a semicircular section of the convex half of the intestine near the point of union of the mucosa and submucosa, to the mucosa and *submucosa of* the unstripped end. It is mucosa. The epithelial elements of the mucosa are perfect. In the connective tissue structure of the mucosa is more *inflammatory* reaction than in any section yet examined. The muscularis mucosa is in two coats, the longitudinal coat being the heavy one. The submucosa shows considerable inflammatory reaction. The circular muscle is filled with cells of inflammation, the fibers being considerably displaced. The longitudinal muscle shows the same as does the circular. The sections are evidently beyond the point of suture, i. e., in a region not split for the flap.

Section C.—These sections are just up the cuff from the line of suture of the mucosa. They show everything shown in "B" and in addition, external to the longitudinal muscle coat, is a coat of fibrous adhesion, and outside of this are the two muscle layers of the cuff.

Specimen 3.—A piece of larger intestine than in the other specimens. The length of the piece is seventeen centimeters. The length of the discolored area is two centimeters. The bowel has been cut longitudinally just above the proximal end about 0.3 cm. below it, 0.5 cm. lower down, 1 cm. lower down, the last being outside the line of discoloration.

Sections were made as follows: A, longitudinal section through the cuff. B, the convexity of the bowel about the point of union of mucosa. B¹ near B.

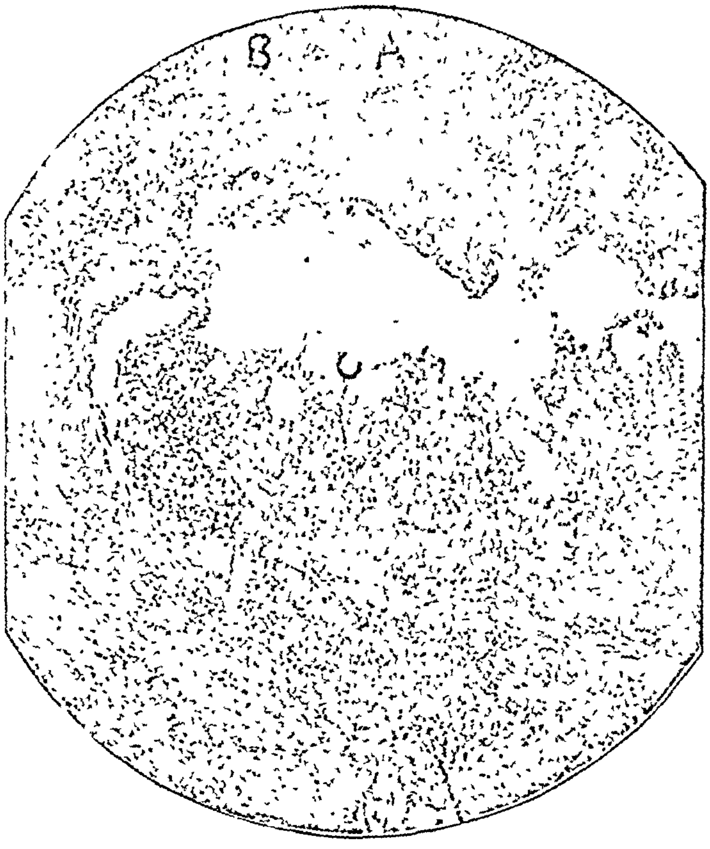

Fig. 5 —a, Mucosa b, Muscularis mucosa c, Thread.

Section A.—This is a longitudinal section near the tip of the cuff. The mucosa, muscularis mucosa, submucosa and longitudinal muscle are quite normal, showing very little inflammatory reaction. The line of union between the longitudinal muscle and the circular muscle of the cuff shows the following: The space covered is about 50 mikromillimeters. It is filled in by a loose reticular fibrous tissue. The fibers have no uniformity of direction. There are only a moderate number of blood vessels. These are young. There are many cells around the embryonal vessels The vessels that I identify as such run lengthwise of the intestine The two muscle coats of the cuff show about as much inflammation as the muscle coats of the intestinal wall. The serosa is thickened by inflammatory reaction until it is about as thick as one of the muscle coats.

Section B.—Longitudinal through the point where submucosa and mucosa of one side are joined to the intestinal wall of the other. The mucosa is perfect except for leucocytic infiltration. There is a deep V-shaped dip at the point of union, the apex being toward the muscle. Around the apex of the V runs the muscularis mucosa. The submucosa is also continuous. It is thin at the apex of the V. The circular muscle of the side is continuous and into the other. This is true of the longitudinal muscle and the serosa. The muscle coats of the other side come into the inverted V and turn up to form one of its sides.

They are joined to the circular muscle of the other side by a small amount of fibrous tissue. (The threads are knotted in the lumen and are firmly held in the wall.) All of the coats contain large numbers of leucocytes.

Section B.¹—Circular beyond the line of sutures. This shows as indicated for Specimen 2, except that there is greater leucocytic infiltration in each of the coats.

Specimen 4.—This was a piece of intestine, split longitudinally. Microscopically we do not find any evidence of the operation procedure, though this is probably due to our not finding the proper area for section. There is a heavy wall of the usual coats. One half or more of the specimen has a serous coat that shows some peritoneal thickening. The other portion is not so covered.

EXPERIMENTS ON DOGS.

I have performed 75 primary operations on dogs, with the following results: 72 dogs recovered and 3 died, a mortality of 4 per cent. The convalescence in every case was short, the dogs being in every instance turned into the general ward at the end of forty-eight hours. The following is a report of the cases that died:

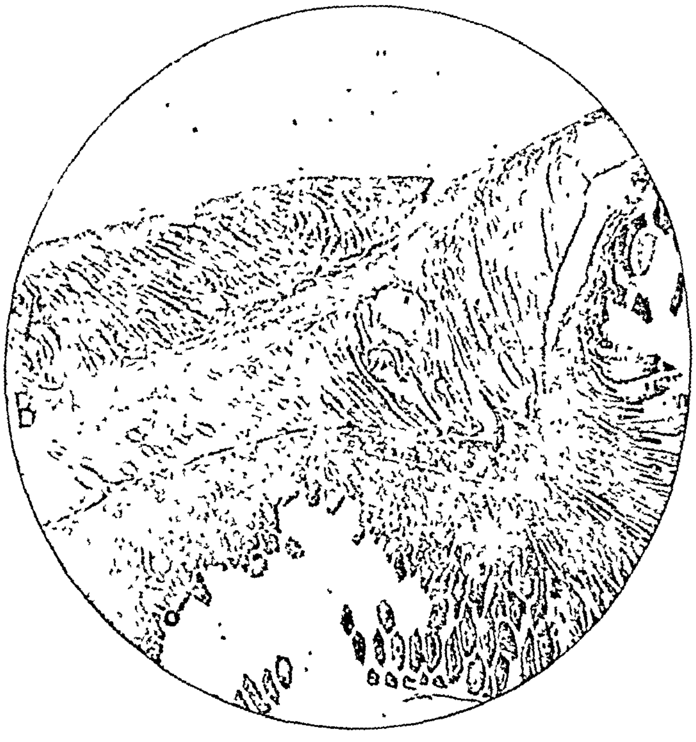

Fig 6 —a, Cuff. b, Line of union

Case 1—Dog No. 36 died five days following operation. Cause of death was general peritonitis. The great omentum was infiltrated with blood and pus, and was adherent to the cuff. Free pus was found in the peritoneal cavity. The intestines were not much distended, but were agglutinated together in several places. The site of operation showed the cuff rather dark, but union of the cuff to the underlying bowel wall macroscopically seemed good. A section of intestine involving the site of union was removed, and examined macroscopically, but no evidence of non-union was discovered. The intestine was gently distended with water, but no leakage was found. The cause of death was believed to be an infection from without, due to a faulty technic.

Case 2.—Dog number 48 died four days following operation. The cuff was distended with blood and pus, a perforation was found in the cuff in the line of union of the proximal end of the bowel to the stump, with positive evidence of leakage.

Case 3.—Dog No. 62, died thirty-six hours following operation. No evidence of peritonitis. The appearance of cuff was good, and was seemingly well adhered to the underlying bowel wall. On section the intestines were found quite well filled with blood, showing that death was due to hemorrhage.

Thirty dogs were reoperated on at periods varying from two to thirty days following the primary operation, with two deaths, a mortality of 7.5 per cent. The deaths occurring in dogs operated on at the end of forty-eight hours following the primary operation, and in each instance within twenty-four hours.

CONDITIONS OF THE CUFF FOUND.

In nearly every instance there were slight adhesions of the omentum to the cuff. The union of the cuff to the underlying bowel was good in every instance. In one instance the intestine above and below the cuff for a distance of five or six inches was adherent, making a bend in the intestine just below the cuff, but in no way obstructing the lumen of the bowel. In every respect the results were universally good.

WORK ON THE HUMAN.

I have only used this method in two cases, in the one a somewhat modified technic was followed, in the other the same technic, as above described, was adhered to.

Case 1.—Mr. B., 50 years of age, was operated on Feb. 6, 1903, for the removal of a tumor in the region of the sigmoid flexure of the colon. The tumor, with several inches of the intestine, was removed. The proximal end of the intestine, which was to be covered with the cuff, was denuded of its serosa, so that the cuff came in direct contact with the muscularis. The patient made an uninterrupted recovery. The tumor removed proved to be an adenocarcinoma.

Case 2.—Miss B., aged 20, had been operated on by the writer five months previously for the relief of chronic obstruction of the bowels, due to tubercular peritonitis. The patient was relieved of the obstruction, improved in general health, and it seemed for a time that her ultimate recovery was assured. Feb. 1, 1903, about five months following operation, she again developed pronounced symptoms of intestinal obstruction. Her condition grew worse from day to day, although slight bowel movements were secured by the use of the high rectal tube. February 12 she had stercoraceous vomiting, and a fecal discharge made its appearance in an abdominal fistula remaining from the previous operation.

Although the condition of the patient could hardly be more extreme, and but little hope could be given her of an operation benefiting her, yet she was desirous of the few chances that it might offer. The abdomen was opened in the median line. The intestines were greatly distended and very much adherent to the parietal peritoneum, and greatly matted together. The site of obstruction was searched for and found. The fecal fistula was located, the intestine just above the site of obstruction was perforated in two different places, so that it was necessary to resect about six inches of it, as it was impossible to attempt its repair. There was no difficulty in obtaining the cuff, the above described method being practiced in every detail. The time occupied for the complete resection was ten minutes. In the further liberating of the adherent intestines a large tear was discovered in a badly ulcerated area, and a second resection of probably four inches of intestine made.

The second resection was a little more difficult on account of adhesions and the extensive pathology in the mesentery; however, it was accomplished in a reasonably short period of time. The patient died at the end of thirty-six hours. A postmortem was denied, so that we can not say as to the behavior of the parts of the bowel united.

The method of operating had nothing to do with the results in this case, as it was evidently hopeless by any method of procedure. It has, however, demonstrated that a cuff can be readily formed of pathologic tissue and that the method is applicable in all cases where resection of the intestine is necessary.

INTESTINAL RESECTION,

WITH A REPORT OF SIXTEEN CASES: NINE WITH THE MURPHY BUTTON AND SEVEN WITH THE SUTURE.*

JAMES H. DUNN, M.D.
MINNEAPOLIS.

With the exception of small lesions toward the free border of the tube, surgical repair of the intestines usually implies a resection more or less extensive, hence the title intestinal resection has seemed more nearly descriptive of the matter on which it is my purpose to elicit discussion than the more usual term "intestinal anastomosis."

Every surgeon who undertakes even cases of strangulated hernia, intestinal obstruction or penetrating wounds of the abdomen, as well as all who open the abdomen for whatever cause, must be prepared to face, often in the most unexpected manner, a resection or repair of the intestinal canal. In the vast majority of cases intestinal surgery is decidedly emergent. The urgent nature and comparative rarity of such operations in any one surgeon's practice renders a perfect technic exceedingly difficult. To skilfully execute such an operation on a moment's notice under the most varying conditions, and perhaps at rare intervals, is a severe task. These considerations lend the subject a somewhat general interest, and place it among those topics which may be frequently discussed with profit even though nothing new be brought out, every surgeon having reason to frequently review his knowledge and rehearse his technic.

The first difficulty one meets is the great multiplicity of methods and the almost endless novelties of technics and operations from which to select. With the mind so full of many theories, and the preparatory drill spread over endless ways, the operator is in the worst possible condition to meet an emergency. Have we not arrived at a point where we can stop investigating new frills and settle on the simplest procedures with advantage?

During the past six years I have had occasion to resect the intestine 16 times, as follows: For strangulated hernia, 3; for fecal fistula, 3; for sarcoma of the small intestine, 2; for carcinoma of the cecum, 2; for carcinoma of the sigmoid, 2; for intussusception, 1; for gunshot wound, 1; for injury during operation, 2. In these the Murphy button was used 9 times, with 3 deaths; the suture 7 times, with 1 death.

The somewhat prodigious number of methods for uniting the bowel may be first divided into three general classes: First, mechanical appliances, to remain in the intestine; second, pure suture methods; third, special appliances to facilitate suture, and then to be removed.

The latter class, to say the least, belongs to those things which are more ingenious than necessary. For my part I do not use them, for many reasons, one of which is perhaps quite sufficient, viz., as good work may be done more conveniently without as with them.

Mechanical means versus the suture in intestinal anastomosis is often debated pro and con. As a simple general proposition, this is manifestly unjust. Possibly all anastomoses may be made by the suture, but certainly in some localities and under some conditions a mechanical means is occasionally preferable. On the other hand, there are many situations and conditions to which mechanical anastomosis is entirely unfitted. Therefore, I conclude that the minimum of methods for good intestinal work is a good mechanical and a good suture method. The practical surgeon will therefore select what he believes to be the best mechanical method and the best suture method, master all the details of each, and be prepared with materials and by occasional rehearsals for the skilful execution of the method best adapted to the situation.

UNION BY MECHANICAL MEANS.

Doubtless any one of several buttons, bobbins, mats or what-not, may be used with more or less success, but increasing experience shows the Murphy button to be on the whole the most practicable. It is cheap, easily preserved indefinitely in readiness and has been used with success and increasing frequency in all parts of the world. Whatever theoretical objections may be conjured up against it, it has probably more success and as few failures to its credit than any other method of anastomosis, when applied properly to proper cases. Of my 9 resections with union by the Murphy button 3 died. One, Case 6, would surely have died despite any method of anastomosis. In one case, No. 9, I was led by the almost moribund condition of the patient to use the large button in an end-to-end union of the sigmoid, though it is generally recognized that the large intestine is not safely united by the button. This death, if due to any operative fault, in no way condemns the button for use in proper cases. In one case, No. 7, an end-to-side anastomosis after resection of the cecum for a very large carcinoma, in a very fat and flabby woman, the death from sepsis and nephritis on the thirty-first day, long after the button had passed, and without any bowel disturbance, makes it probable that the method of union was not at fault. In Case 5 a temporary fecal fistula followed the use of the button in an end-to-end anastomosis of the small bowel, for sarcoma. I have reason to believe that the fistula took place at the mesenteric border. The mesentery was considerably thickened and some difficulty was found in properly adjusting it within the button. Under these conditions either a very much larger amount of intestine should be resected or the suture used instead of the button. The ultimate result in the case has been entirely satisfactory so far as the anastomosis is concerned. In the remaining five button cases the immediate and subsequent course was without any complication.

The duodenum, owing to its fixed position and lack of peritoneal covering, is naturally excluded from end-to-end anastomosis by the button. The large intestine, for many reasons, both anatomic and physiologic, is not adapted to anastomosis by mechanical means. It is less richly supplied with blood vessels, its walls very variable in thickness, the appendices, epiploicæ and its mesentery often thickened and clumpy with fat and considerable portions not covered by peritoneum. Its contents are much thicker and more liable to block mechanical contrivances and its peristalsis comparatively feeble. Hence, with the exception of end-to-side anastomosis between the small and large intestine, the suture should practically always be used. In the unfixed portion of the small intestine, a good union is possible by either button or suture, but, on the whole, I believe the button anastomosis has the most points of excellence: First, it may usually be executed somewhat more rapidly; second, if skilfully applied is evidently primarily as safe in this location as suture. Third. After the button has passed the intestinal wall is left in better condition than by suture. In all suture methods where silk is used there is either for a long time or permanently left in the bowel material with decided possibilities of trouble. With the button, the primary healing once over, the most perfect conceivable condition is usually left and the condition is uniform. As much can not be said of any suture in any case and the results are materially far from mathematically uniform, even in the same surgeon's cases. The most skilful operator will vary a little in the amount turned in and in the regularity of his suture. The mechanism once properly placed cuts by its pressure to the same line. The objections to the button in this locality are mostly theoretical or drawn from very exceptional ill results or cases of faulty technic. When it may be said that any other method is absolutely perfect and without occasional mishap, the practical surgeon may give greater weight to the theoretical objections of a foreign body in the intestine, to isolated failures to pass, or to exulceration of the button, despite the many hundreds of successes at the hands of hundreds of surgeons, many of those of little experience, and the growing tendency of many of the very greatest surgeons at home and abroad to use this method in appropriate cases.

UNION BY SUTURE.

The suture has a much wider application. It may be used in practically all cases to which the button is applicable. In the duodenum and in the large intestines it has for anatomic and physiologic reasons practically the whole field. Hence a surgeon may nearly or quite dispense with mechanical means of anastomosis, but a good suture method is a necessity. While we undoubtedly owe a very large measure of our success to experimental work and the fundamental principles have been thus established, yet experimenters have borrowed an enormous amount of unnecessary trouble about lesser matters of which Nature takes little notice. The necessity of peritoneal approximation, the length of intestine which may safely be resected, the degree of narrowing which is permissible, the difficulties of the mesenteric border, etc., were early elucidated and are essential, but the fears of penetrating all the coats and the special dangers of the knot of elbowing in order to increase the caliber, etc., have been considerably overdone. I feel sure from much personal observation—having followed up individuals for years whose intestines were closed up with very rudimentary needlework—that the fears of some experimenters are not entirely well founded.

Of the 7 unions by suture, 4 were by the Connell method. The Connell suture appeals to me as by far the best suture up to date; first, a continuous suture is the safest; second, penetrating all coats it is the strongest and surest; third, it is a simple set procedure, capable of an unvarying technic from start to finish, with no change of stitch, and no apparatus but needle, thread and fingers; it is capable of greater rapidity than any other method except the button—the easiest and simplest of all, except at its finish. The closure of the last third, and especially of its last stitches, is, of course, somewhat difficult, but after sufficient drill probably not much more so than some part of any competent intestinal suture. It takes the best care of the weak point, the mesenteric border, while the gut is open. With one exception it is, for me, the *ne plus ultra* of intestinal sutures, viz., experimental work and autopsies show that for a very long time, at least two or three months, the thread remains encircling the bowel wall or hanging into the intestine. While I am unable to point to any serious result demonstrably having followed this state of affairs, it is certainly not an ideal condition, and one which would seem pregnant with as many pathologic possibilities as the shorter stay of a foreign body in the case of a button. It is quite startling to find at the autopsy, thirty-one days after the resection, so much thread imbedded in the whole circumference of the otherwise beautifully restored bowel, as was observed in Case 13.

All the unions were end to end, excepting the two resections of the cecum, where end-to-side anastomosis was employed. When the resected ends can be easily approximated without tension and the mesentery is in a normal condition, end-to-end union would seem to be preferable to lateral anastomosis, as it more nearly restores the organs to normal conditions. Pathologic changes in the mesentery may sometimes render it desirable to close the ends by purse-string sutures and make a side-to-side union. When this is done with but little overlapping so that the blind ends are very short, antiperistaltic union is probably without very serious objection. However, an isoperistaltic union would seem preferable whenever practicable under all circumstances, and quite necessary if the blind ends are of much length. In resecting median portions of the small intestine, it is often difficult to quickly establish with entire certainty which is the proximal and which the distal limb of the loop. If an end-to-end union is to be made this is of no consequence, but in case of a lateral approximation it calls for a decision which further complicates the operation. I would therefore not choose lateral anastomosis except in cases in which some pathologic or anatomic condition of the mesentery rendered the end-to-end approximation unsafe.

CONCLUSIONS.

1. Suture is the most indispensable and generally applicable method of anastomosis in intestinal resection.

2. The Murphy button is equally useful, if not preferable, under certain conditions, but very inferior under others. For the end-to-end union of segments of normal small intestine, or the end-to-side anastomosis of healthy small and large bowel, it gives results unexcelled by any other method. In unions of the larger intestine it is so far inferior to suture as to be practically contraindicated. Pathologic changes in the small intestine or its mesentery which render the perfect application of the button difficult or such as would probably disturb the course of healing, should be united by suture.

3. Of suture methods that of Gregory F. Connell is incomparably the best; is, in reality, the simplest; a single row of continuous suture, all within the gut, the most likely to be even, strong and tight, with the smallest and most even diaphragm, admits of the easiest and most perfect dealing with the mesenteric border and is capable of a simple invariable technic.

4. It is especially desirable to choose the fewest and simplest means compatible with the best work, because intestinal operations occur at rare and irregular intervals as emergencies in the hands of many surgeons, and the little conveniences which enter into highly specialized operations of repeated daily execution are for the most part worse than impracticable.

NARRATION OF CASES WITH USE OF BUTTON.

Case 1.—Miss H., age 27. Strangulated femoral hernia. Operation only twelve hours after onset of symptoms. Three inches of small intestine gangrenous. Resection of five inches; end-to-end anastomosis with Murphy button. Prompt recovery. The button passed on the eleventh day. No return of hernia. Now, six years after, health perfect.

Case 2.—Fecal fistula from inflamed umbilical hernia. Mrs. B., aged 46, enormously fat, had a large umbilical hernia of ten years' standing. Three months before coming under my observation symptoms of inflammation and finally of intestinal obstruction had appeared. After eleven days of expectant treatment an abscess had broken through and pus and feces had discharged. A large fecal fistula had since discharged nearly all the bowel contents, only occasionally a little passed *per anum*. The abdomen was opened, the adhesions separated, the hernial sac and a portion of the omentum was removed. and three inches of small intestine resected. End-to-end union with the Murphy button and radical cure of hernia with silver wire. A large area of eczematous skin around the fistula was excised and the skin closed transversely. The button passed on the ninth day. The recovery was uninterrupted, excepting a slight superficial infection, which did not lead to removal of the deep wire sutures. Her health has remained good, no relapse of hernia and no trouble from the wire sutures at last observation, four and one-half years after operation.

Case 3.—Fecal fistula. Mr. M., a farmer, aged 32. Had right inguinal hernia of long standing. About five weeks before coming under observation strangulation occurred, and Drs. DuBois and Hilbert of Sauk Center operated, after which the patient did well and was entirely relieved for ten days, when symptoms of strangulation again suddenly appeared. After a week of vomiting and inability to pass gas or feces, Drs. DuBois and Hilbert reopened the wound and incised a knuckle of adherent small intestine forming an artificial anus.

The patient then again did well for two weeks, when obstruction again, for the third time, became complete. I was then called by Dr. DuBois. The patient's general condition was now bad. He was emaciated and weak, and the operative field was rendered uninviting by recent operations and the recent fecal discharges which had constantly bathed and irritated the skin for two weeks. The operation was made at the patient's cottage under poor surroundings. On reopening the abdomen it was found that a small knuckle of intestine which was attached to the abdominal wall and the seat of the artificial anus had twisted on its axis, leading to complete obstruction. This loop was resected and an end-to-end anastomosis made with the Murphy button. The abdomen was closed with figure-of eight silkworm-gut sutures, and the patient made an excellent recovery with only some slight suppuration in the wound. The conditions for primary union were as unfavorable as could be imagined. I examined the patient two years after the operation and he was well and free from hernia.

Case 4.—Gangrene due to strangulated hernia. Male, laborer, aged 28. City Hospital. The patient entered with a large inguinal hernia, strangulated since six days. The scrotum was red, swollen and inflamed and the patient profoundly septic. On opening the sac about three feet of small intestine was completely gangrenous. Resection of three and one-half feet. End-to-end anastomosis with Murphy button. The wound was left partly open and the wound and abdomen drained. Death followed in forty-eight hours, due to peritonitis and sepsis. Postmortem showed the anastomosis to be perfect, and that the button was in no way responsible for the death. Probably it was a mistake to have resected at all. Under such conditions again I would lay open the sac without a general anesthetic, and if the patient recovered make a subsequent resection, as in Case 2.

Case 5.—Sarcoma of small intestine. Mrs. B., musician, wife of a physician, aged 44. In August, 1896, she began to have looseness of the bowels, and ever since off and on had had spells of looseness, becoming worse each year. In November, 1902, she had a very bad diarrhea, which reduced her strength and weight very rapidly. This diarrhea was of a peculiar character, i. e., it was worse after lunch and still worse after dinner and all night, but from 9:30 a. m. to 1:30

p. m. it was not very troublesome. There were usually from eight to ten movements a day. There was no pain, but a very great quantity of gas was passed, the feces very thin and horribly offensive and of the consistency of muddy water. She was very anemic, greatly emaciated and weak.

I first saw her on the first of February, 1902, and on physical examination could distinguish a mass to the right of the uterus and attached to it, which was apparently of the size of a small fist. I suspected the bowel was involved in this mass, and advised exploratory incision. The operation took place at St. Barnabas' Hospital, Feb. 12, 1902. On opening the abdomen this mass was found to consist of a very much enlarged and dilated coil of small intestine attached to the uterus. The mesentery of the intestine was also infiltrated and thickened. I removed eight inches of the intestine and its corresponding mesentery and made an end-to-end anastomosis with the Murphy button. The patient did remarkably well for a few days, but on the twenty-first she developed some temperature. The abdominal wall was opened slightly and a fecal fistula made its appearance. For a few days a large quantity of feces was discharged through this wound. March 4 the patient insisted on being taken in the ambulance to her home. On March 6 the button was passed, and March 11 the fistula closed permanently, and she was up and about the house March 21, from which time she made a fairly satisfactory recovery.

The portion of intestine removed was believed on gross appearances to be a chronic inflammatory process and the specimen was sent to the laboratory of the University of Minnesota. Professor Wilson reported it to be a sarcoma. The patient is still—thirteen months after the operation—in very good health. At the time the union was made considerable difficulty was experienced in bringing the somewhat clumsy mesentery satisfactorily within the button, and I remember using an extra stitch through the mesenteric border and tying it around the button stem. This was doubtless the point where the fistula took place. It might have been better to have resected a much longer loop, thus securing a more normal mesentery or to have used the suture at the point chosen.

Case 6.—Carcinoma of cecum. Mrs. S., aged 36. For several months has complained of pain and tenderness in right inguinal region and of alternating constipation and diarrhea. There is a tumor in the region of the appendix and the condition thought to be some anomalous form of appendicitis, perhaps tubercular. On operation, carcinoma of the cecum was found. About six inches of the ascending colon, the cecum and four inches of the ileum resected. End-to-end anastomosis with the Murphy button. Uninterrupted recovery and health good when last seen, one and one-half years subsequently.

Case 7.—Carcinoma of cecum. Mrs. L., French, aged 38. Mother of six children, youngest 2 years of age. Previous health excellent, excepting loss of control of bowels from a complete laceration of the perineum. She now wished this repaired, as she had been led to believe it was the cause of her present illness. About one and one-half years ago she began to have pain and diarrhea in the morning, with nausea and pain in the stomach. On examination I found a large woman, a very fat abdomen, and a very large, hard tumor, much larger than two fists, in the right iliac region. Complete laceration of the perineum. Diagnosis, probably carcinoma of the cecum.

Ten inches of the cecum and ascending colon and a portion of the ileum was resected with much difficulty, owing to the advanced stage of the very large growth. End-to-end anastomosis with the button. The button was found in the vagina five weeks later. For two weeks the patient did very well, she then developed temperature, suppuration in the large and deep external wound (the fat was about four and one-half inches thick at this point) and nephritis, dying seven weeks after the operation. No autopsy was permitted, but the death was clearly not due to the method of union, nor, indeed, to the anastomosis at all. The enormous wound in an obese and bad subject became infected, and sepsis and nephritis finally exhausted her resources.

Case 8.—Strangulated femoral hernia. Mrs. M., aged 46, German. Had been ruptured for several years, and for the last two years the tumor had been irreducible, hence, despite symptoms of strangulation, the patient and her family physician had refused to look on the hernia as the cause of the constant vomiting until the fourth day, when I was called in consultation, and insisted on immediate operation. The sac was chiefly filled with adherent omentum, but a very small knuckle of small intestine had recently slipped in, become strangulated and was found gangrenous. Resection of three inches. End-to-end anastomosis with button, drainage of external wound. Prompt recovery.

Case 9.—Stenosis of sigmoid from very small annular carcinoma. Mr. B., laborer, aged 45. Entered St. Mary's Hospital in March, 1900, complaining of a recent right femoral hernia, on which I operated, finding the appendix vermiformis and some omentum in the sac. The appendix, omentum and sac were removed, and he made a good recovery. While at the hospital it developed that he had had some slight difficulty in getting his bowels to move satisfactorily, but this seemed to be better on taking some laxative, and he left the hospital at the end of three weeks.

I saw nothing further of him until July, 1901, when I was called by his attending physician, Dr. Ringnell, and learned to my surprise that he had been having increasing trouble with his bowels since leaving the hospital, until of late he was having frequent attacks of complete obstruction, lasting for days at a time and in the intervals getting liquid movements with great difficulty. He was greatly emaciated and thin and seemed almost *in extremis* from pain, vomiting and distension. Chronic obstruction in the lower large bowel was diagnosed and immediate operation urged. The patient, however, stubbornly refused until September 1, when he consented to return to the hospital. He was then very weak and death very near. On opening the greatly distended abdomen a very small annular growth in the sigmoid, less than an inch in extent, was found, reducing the caliber of the intestine to that of a very small lead pencil. The gas and liquid feces were evacuated by introducing a glass tube into the intestine above the growth, and about four inches resected. On account of the almost moribund condition of the patient I chose the large Murphy button for making the end-to-end anastomosis. Death from peritonitis and sepsis in thirty-six hours. Autopsy showed button plugged and a leak from distension. The first mistake was the patient's in refusing operation for months after it was clearly necessary and strongly advised, the second in using the button under these conditions where suture is always indicated.

Thus of the 9 cases united by the button, 3 died, 1 clearly because no resection should have been undertaken—the patient probably would have succumbed in any event, but the only hope would have been in incision of the sac, which might have been done without anesthetic. In one the larger button was used in an end-to-end anastomosis of the sigmoid, and although the patient was in extremis it is quite possible that he might have recovered by the suture. This is the only case in which I have to regret the method of anastomosis chosen. One dies six weeks after operation, with extraperitoneal suppuration in the abdomen and nephritis. There is no reason to believe the method of anastomosis had anything to do with the result.

NARRATION OF CASES OF UNION BY SUTURE.

Case 10.—Intussusception, necrosis at the neck. A boy, 6 years of age, symptoms of obstruction for eight days. Dr. Glenn was finally called and diagnosed intussusception. On opening the abdomen a large quantity of rather dark serum escaped. About a foot of the ileum invaginated into itself. The neck was at about the point of Meckel's diverticulum, of which there appeared to be a remnant. The invagination was reduced with considerable difficulty and a small necrotic area at the neck necessitated resection of a small portion of the gut. End-to-end anastomosis—Czerny-Lambert suture. Recovery without complication.

Case 11.—Pistol wound of abdomen. W. J., aged 23. Shot in the abdomen with pistol at short range. Wound of entrance two inches to the right and a little below the umbilicus. No wound of exit. Operation twelve hours after injury. Seven perforations of small intestine, closed with continuous Lembert suture. Resection of twelve inches on account of injuries at the mesenteric border. End-to-end anastomosis with Czerny-Lembert suture. Recovery and perfect health two years after.

Case 12.—Sarcoma of the small intestine and uterus. Mrs. M., German housewife, aged 38. In May, 1901, was taken with cramps in the bowels, pain radiating toward the center. She vomited for eight days more or less and there was much distension and gurgling in the bowels, and irregular diarrhea during the past four months. On examination a considerable tumor attached to the uterus could be made out. It was fairly movable and had been mistaken by several for a fibroid of the uterus. I was not just clear what the condition was, but believed it was primarily uterine with attachment to the bowel, and advised an exploratory incision.

Sept. 7, 1901, the abdomen was opened and a loop of small intestine about ten inches long and its mesentery was found involved in a new growth. This mass was firmly attached to the uterus, which was also invaded by the growth. Recognizing the condition as malignant and probably past successful removal, a side-to-side anastomosis of the two limbs of the loop of intestine above the growth was undertaken. After the button was introduced it was found defective and had to be taken out. I then decided to remove the growth and some sixteen inches of small intestine and its mesentery, the uterus, tubes and ovaries, and a portion of the base of the bladder, which were resected in one piece. End-to-end anastomosis of the resected intestine by Connell suture. The time of the whole operation from entering to leaving the operating room was one and one-half hours.

The patient made a good primary recovery, leaving the hospital twenty-seven days after operation to go to her home in Dakota. Her health was greatly improved for some months. Six months later the growth returned and at last reports she was failing rapidly. The specimen removed was submitted to Dr. White of the pathologic laboratory of the University of Minnesota, who reports it to be a lympho-sarcoma of the small intestine.

Case 13.—Mr. H. Carcinoma of the sigmoid flexure of the colon; resection of six inches; end-to-end union by the Connell suture. The patient's health had been excellent until about one and one-half years ago, when he began to experience considerable difficulty in moving the bowels, obstruction symptoms not very severe until the past four months; he has attacks of pain before the bowels move, and for the past six weeks it is with great difficulty that they can be moved at all. By taking much physic and repeated enemata he is enabled to overcome the obstruction. The diagnosis was partial obstruction in lower colon, probably from carcinoma. March 4, 1902, resection of six inches of the sigmoid and end-to-end anastomosis with the Connell suture. The abdominal wound became slightly infected superficially with colon bacillus and discharged moderately for ten days, otherwise the after-course was uneventful. March 31 the patient was apparently well, having been up and dressed for two days. He had made all arrangements to leave the hospital for his home. some two hundred miles distant, on the following day, when he was seized with an apoplectic stroke, from which he died April 4, thirty-one days after the operation. Autopsy showed the operation wounds perfectly healed and the anastomosis was perfect with no intraperitoneal adhesions. On dissecting the intestine the whole suture was found intact in the walls of the intestine, forming a circle entirely around it. None of the stitches had so far been thrown off into the bowel.

Case 14.—Gangrenous strangulated hernia. Sister A., a Little Sister of the Poor. Had a slight femoral hernia of long standing which had been strangulated for at least twenty-four hours. Several unsuccessful attempts at reduction by taxis had been made. On opening the very large sac about ten inches of small intestine was found to be gangrenous. As it was difficult to bring down a sufficient amount of bowel to make a good resection without cutting through Poupart's ligament, the abdomen was opened by a second incision above the ligament. in the outer border of the rectus muscle, the operative field in the abdomen well packed off with gauze, the loop drawn into the abdomen and brought out through upper incision, and twelve inches resected. End-to-end union with Connell suture. The hernial sac then removed and hernial wound closed as usual. Uneventful recovery, patient leaving hospital seventeen days after operation.

Case 15.—Mr. M., a young German farmer, when seen had obstruction of the bowels for four days. His condition was said to have been good until the last six hours, since which he had rapidly collapsed. He had had two very severe attacks of appendicitis ten years before, since the last of which his health had been excellent, until the sudden onset of symptoms of intestinal obstruction. Patient evidently failing rapidly every hour—cold extremities, rapid, feeble pulse, great distension. Nevertheless, the abdomen was opened at his desire. The small intestines were found bound down into the bottom of the pelvis by broad bands, so much so that they appeared to have a mesentery on both sides. The distended intestines could not be turned out of the abdomen on account of their attachment to bottom of the pelvis, hence there was great difficulty in dividing the bands. A knuckle of intestine was so injured that resection of about two feet became necessary, hurried end-to-end anastomosis, with Connell suture rather imperfectly done and reinforced at last third by continuous Lembert. Patient expired within an hour. It is needless to say the result has no bearing on the method of anastomosis.

Case 16.—Mrs. J., aged 32. Had a violent appendicitis and pelvic suppuration some months previously. The abscess had been drained, but appendix not removed. Recovery never complete. At secondary operation intestines matted together in bottom of pelvis by old, well-organized adhesions, small pelvic abscess; appendix removed and many bands and adhesions severed, finally one knuckle of intestine so injured in several places that resection was deemed safer than isolated repairs in its diseased condition. Resection of almost six inches of small bowel, end-to-end anastomosis, Connell suture. Pelvic drainage. Recovery without complications.

Of the 7 unions by suture, 6 recovered; 4 were by Connell suture, with 1 death from collapse within one hour.

DISCUSSION

ON PAPERS OF DRS. CAMPBELL AND DUNN.

Dr. A. F. Jonas, Omaha—The indications for this operation are so plain that they need no discussion, but the methods for doing an end-to-end approximation is a question that involves a multiplicity of ways. The inventive genius seems to be so prominent in American surgeons that no sooner has some one proposed a new method for the relief of any particular affection than the American man is not satisfied to try that particular method, but he immediately goes to work and tries to invent a method, hoping to get something better and something newer. For my own work I have only employed two methods; the first is the mechanical device practiced by Murphy, the second the simple suture. I desire to call attention to four points: The first is to get the approximation of the intestines at the point where it joins; the second, to leave no knots on the outside of the intestines; third, it must be watertight; and, fourth, it must be airtight. Now, with these four things carefully carried out, in a practice requiring a simple form of technic, the simple suture will be the best to use. The only way to do surgery is first to study the pathology, and in the operation do not use any methods that will lead to this pathology in the smallest possible way; if possible, do not use any mechanical devices for the purpose of holding the intestines in position.

Some years ago, Nicholas Senn described in The Journal of the American Medical Association, fifty or more appliances for the purpose of producing end-to-end union. Of all this long series, there is probably only one that is used to any extent at the present time, and that is the Murphy button. Of all the many sutures with which I have become familiar I employ none but the Connell suture, as it is the most easily applied, most satisfactory, gives the best results and leaves the knots all on the inside, thus giving no opportunities for the subsequent formation of adhesions in the intestines. All the forms of sutures which leave the knots on the outside favor adhesions with the other parts of the intestines, or with other organs necessitating secondary operation. In order to properly apply any form of intestinal suture we need to practice that form more or less constantly. To do the operation with the Connell suture will require a certain amount of preliminary practice as with any other suture. It is practically impossible for any man to stand beside the operating table and see anyone else perform an operation and then go home and do the work without preliminary practice. What would you say if a tailor simply stood beside another tailor and watched him apply the stitches to your coat? Would you then expect him to make seams accurately and firmly? Why should you expect any more a man to be able to suture an intestine simply from what he reads in books or from standing beside another operator? The Murphy button, simple as it is in its application, must be practiced primarily on the dog, and certain details must be memorized before its use can be undertaken in the human subject. My plan is to use the Murphy button in all cases where the structures can be snugly drawn together between the two parts of the button. Where the structures are too thick, such as the large intestines, I employ the suture method. So far as Dr. Campbell's method goes, I have the objection to it that he still leaves the knot on the outside.

Dr. J. Shelton Horsley, El Paso, Texas—In regard to the term "intestinal resection," it seems to me there might be still further improvement. Resection means simply cutting out a portion of the intestinal canal, and has no reference to the subsequent joining of the divided ends, which is really the main and most important portion of the procedure. "Intestinal anastomosis" is also objectionable when applied to an end-to-end union. Anastomosis means that an obstruction in the main channel is compensated for by some more or less indirect route, as in the case of small branches of blood vessels taking up the circulation when there is an obliteration of the main channel. When, however, this obstruction in the main channel is removed and the direct current re-established, as in the case of end-to-end union in intestines, the term anastomosis is clearly inapplicable. "Circular enterorrhaphy" means merely suturing of intestine in a circular manner. In the operation for prolapse of the rectum, in which after abdominal section a portion of the sigmoid is drawn up and sewed to the abdominal wall, if this sewing is done in a circular direction, the term "circular enterorrhaphy" could most assuredly be used. "Intestinal union" is a term that is open to none of these objections and would seem to indicate the procedure.

In regard to the continuous suture, I have had a limited clinical experience in intestinal suturing, but a rather extensive experimental experience, and have found that this form of suture is by far the most satisfactory. I believe that the majority of operators who have done much experimental work will agree in this. This form of suture has many advantages not possessed by the interrupted. It is a physiologic principle that rest is essential for repair. It is with this idea that splints are used in fractures and wounded parts immobilized as much as possible. The action of a continuous intestinal suture is in the nature of a splint. In end-to-end union, for instance, where interrupted sutures are used, each distension of gas and every wave of peristalsis tends to stretch or relax the portion of intestine between any two interrupted stitches. When a continuous suture is used this strain is thrown, not on the wounded intestine, but on the thread. It is frequently taught, I believe, that all that is necessary to obtain complete union in intestinal suturing is to approximate serosa to serosa. This is certainly a false doctrine, for something else than mere approximation is necessary to obtain satisfactory union in every instance. This conclusion has been arrived at as the result of nine experiments on dogs. In six fine black silk was used and the dogs were killed after one, two, three, four, six and eight days. In three experiments No. 2 braided silk was employed and the dogs killed after four, six and eight days. Two loops of intestine were sutured, as in the preliminary steps of Abbe's intestinal anastomosis, the suture being continuous and running for about an inch and a half in the long axis of the gut. Another row parallel with the first and about one-third inch distant from it was inserted in the same manner. The specimens were removed after the number of days above indicated and sent to a competent eastern pathologist for examination. The condition of the serosa between these rows of sutures was that of perfect approximation, and on account of the continuous suture it would be impossible for this approximation to be disturbed. The pathologist reported that of the first six experiments, in four there had been failure of complete union of that area of intestine included between the rows of suture; in the other two, in which fine silk was used, the union was complete. Of the three experiments where No. 2 braided silk was employed, only one failed to unite completely. The pathologist also reported that there was markedly more inflammatory reaction around the coarser thread. As the conditions of approximation in these experiments were perfect, and as complete union was obtained in less than half of the number, it would seem that something else besides mere approximation is necessary for satisfactory union. Pressure is one of these things that is most desirable and is furnished by such appliances as the Murphy button. This pressure can be obtained by the continuous suture, but not by the interrupted.

Dr. H. O. Walker, Detroit—The methods by which the operation of intestinal resection is to be performed have been outlined by the gentlemen who have read papers and by the gentlemen who have already discussed them. The method given by the first gentleman would strike me as being one (possibly he can do it rapidly) that would take considerable time, while, as the gentleman just preceding said, it leaves some of the knots on the outside. I have had experience with pretty nearly every form of suture and mechanical appliance. I did one end-to-end anastomosis with the Murphy button in the latter part of 1902. I have used the Connell suture in six different cases; one where I removed 14½ inches of the colon, another 8 inches of the ileum, another the ileocecal junction, another 6 feet of the intestine, another at two different points in the descending colon. The first three cases were successful and the last three died, but I do not know that it could have been otherwise, because the condition of sepsis was such as to preclude recovery.

There is no mechanical device that has recently been brought before the profession that is of more value than the McGraw elastic ligature. I have had an experience in 17 cases with that ligature, and in all of the cases it was successful, so far as temporary relief was concerned. Of these 17 cases 122 jejunostomies were performed for malignant disease and 5 for gastroptosis. The use of the ligature as a mechanical appliance is simpler than anything else that we have. Of course, it is not applicable to an end-to-end anastomosis. It can be done quickly and produce no inconvenience. As has already been stated by the former speakers, no man should attempt to use this ligature unless he has practiced either on animals or on the dead intestines. In regard to the application of this ligature, you take a rubber darning needle, about 6 inches long, and be sure that the rubber in the ligature is in good condition, for in those ligatures which have been on hand for a long time the rubber is liable to break. For instance, we are doing a gastrojejunostomy. You take a bite on the stomach about 2½ inches. First, we make an approximation and run the suture of silk around the intestine and the stomach and then we introduce the ligature, draw it through the stomach and come back again on the intestine. After you have got your ligature in position and drawn it up, be sure you have it well on the stretch before you begin to tie.

Dr. J. B. Murphy, Chicago—The technic of surgical approximation is, I think, of lesser significance than the recognition of the pathologic condition of the intestines in, about and below the line of approximation. I believe that by any of the ordinary methods we will get a good and sufficient approximation if we will recognize the pathologic conditions of the intestines, whatever the position of the approximations, and the failures in intestinal approximation rest principally, I believe, in not recognizing that the intestinal wall is infiltrated, and that its action is impaired for a considerable distance above the position of the resection. My attention was called to this in some of the early operations with the button, where I found gangrene following the insertion of the button. No other legitimate outcome could have been expected; no other result could have been secured by any other method. So soon as we learn to remove a sufficient amount of the bowel at the proximal end to leave completely healthy, uninfiltrated intestinal wall, we will have less failures. That accounts, in my opinion, for the failures in many instances.

Dr. Alex. Hugh Ferguson, Chicago—I would like to raise my voice in favor of the promotion of every man who is going to do intestinal surgery. We can get no good by looking on and seeing others do these operations. We have to do it ourselves, and the paper read by Dr. Campbell is, in my opinion, a very excellent one. I have seen him perform the operation. I have looked over the notes very carefully, and I can see the beauties of that operation. In the first place, you have fewer sutures than by any other method. That flap can be rolled back very quickly, and the other sutures on the outside are few and are only the so-called "tack sutures," because they do not go through into the mucous membrane; so that, although they are on the outside of the bowel, they can not do any harm.

The suture which has seemed to me to be the best and that which I have used the most is the one introduced by Dr. Connell. I have used it a large number of times. The last few years I have been using it almost exclusively when I could, but occasionally I would get a little stuck and could not very well use it, and I would fall back on my old friend, the Murphy button. I have used the Murphy button a large number of times, and it has stood me well in some places where a suture could not be applied, for instance, in removing a section from the lower portion of the cecum or the lower portion of the rectum, where you can not very well employ the suture, but you can put in the large size of the Murphy button. In doing the Bacon operation for stricture you can use the suture and the patient does perfectly well. It comes in very well in gastroenterostomy, and, in fact, there are so many applications for it that I would not pretend to mention them now. The McGraw elastic ligature I used in one case where I had done a gastroenterostomy. I had become a little conceited and thought that I would not get a vicious circle. I made the approximation a little high up, so that the gastric current could not help go down. In this case I was mistaken; it would not do that, and consequently I had to open the abdomen again and make an anastomosis between the two arms of the anastomosis. I did that with the McGraw elastic ligature very quickly and it served my purpose. For some little time afterward he had slight trouble with the circle of Willis until the anastomosis was complete.

I would also like to emphasize what has been said by Dr. Murphy, that failures take place more frequently owing to error on the part of the surgeon in selecting the part where the bowel should be removed than from any defect in the technic.

Dr. O. Beverly Campbell, St. Joseph Mo.—It seems to me that the most of the discussion has been on the McGraw elastic ligature and the older methods. In regard to the knots outside the lumen of the bowel, which question was raised by two gentlemen, it was well answered by Dr. Ferguson, and certainly the knot can do but little harm, and it would certainly be far-fetched criticism that would criticise a knot of that character outside the lumen of the bowel. Of course, some surgeons are getting so very technical that it is a question where they will stop. Now we would not have expected this method to have received more than a discussion, but it does seem to me that we should have discussed this method rather than the older methods, as we are looking for better things, and not for the older methods that we have tested and which we know are good. We want something a little bit better.

Fate of Typhoid Bacilli in Beer.—*Professor Surmont of Lille*, France, has been testing the beer made there in respect to its effect on typhoid germs. He found that the cultures of typhoid bacilli added to the beer were all killed in one-half to sixty-seven hours, the bactericidal effect being most pronounced in proportion to the amount of lactic acid in the beer; the acetic acid had also a lesser influence of the same kind. The beer, as it is manufactured, is evidently a hygienic drink, but when water is mixed with it, as frequently occurs, the germs in the water may prove a source of infection. Beer weak enough to allow survival of bacteria becomes more bactericidal as it ripens, as the bacilli in it generate more lactic acid, which in turn has a destructive action on them.

REPORT OF A CASE OF PEMPHIGUS CHRONICUS.*

WILLIAM FRICK, A.M., M.D.
PROFESSOR OF DERMATOLOGY IN KANSAS CITY MEDICAL COLLEGE.
KANSAS CITY, MO.

The word pemphigus is derived from a Greek word, which means a blister. Hence the earlier writers used the term, with some qualifying adjective, for all bullous eruptions. This gave a large number of varieties. More recently the term is more restricted in its use, and instead of some of these varieties we hear of the bullous eruptions of syphilis, impetigo bullosa, epidermolysis bullosa, etc.

This seems to indicate that the work of elimination is going on and the term will in the near future be restricted in its use to some definitely described disease or perhaps several varieties of the same disease. The disease known as pemphigus vulgaris by Hebra, Kaposi and others, or as pemphigus chronicus by Unna, Crocker and others, is the one to which no other name is given, and seems entitled to be distinctly known as pemphigus. It would seem that pemphigus foliaceous is but an advanced or malignant variety of the other. In this paper I will not attempt to consider anything but pemphigus chronicus, as that was the affection afflicting the patient whose clinical history I will try to relate. While this is a rare disease, especially in America, it still occurs with sufficient frequency to make it of great interest to those giving a good deal of attention to skin diseases. This interest is increased by its obscure etiology and by the gravity of the disease. While a large percentage of these cases recover temporarily, we would like to quote Kaposi, who has had a large experience and seems to have studied his cases carefully and observed them for a period of years in order to see the final results He says:

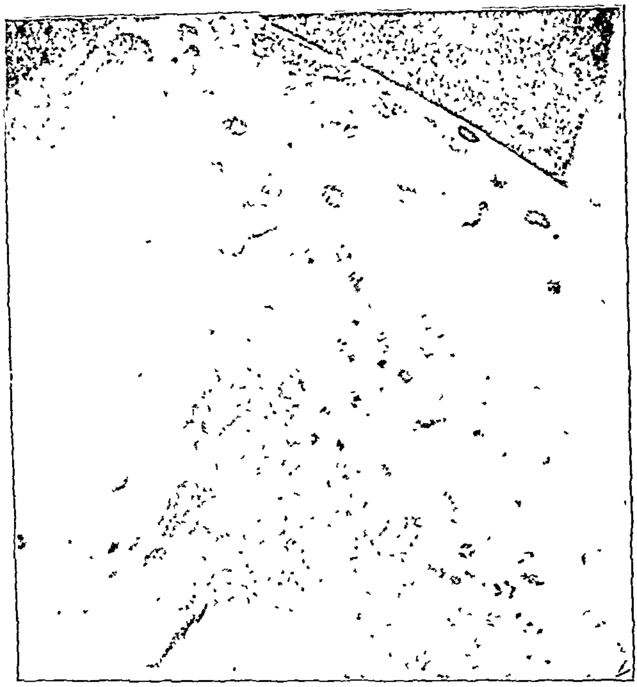

Fig. 1—The eruption on the leg

> In 21 years (1866 to 1887) I saw at the hospital 210 cases, and altogether more than 300 cases. Among 182 cases which were carefully studied there were 35 deaths (with autopsy),

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, W. L. Baum and J. A. Fordyce.

i. e., the mortality under our observation was 17 per cent. The remaining 83 per cent. can only be regarded as temporarily "improved" or "cured" and the majority of them terminated fatally. In my estimation, not 10 per cent. of the cases really recover permanently. (J. C. Johnson's translation of "Diseases of the Skin by Kaposi," p. 399.)

Those cases which lapse into pemphigus foliaceous are considered universally fatal. It occurs to me that until the etiology of a disease is well established, careful and accurate reports of the clinical history of the case may be of value; hence the attempt to report the following as accurately as possible. The case occurred in the practice of Dr. E. Carbaugh, by whom I was called in consultation and given the opportunity to observe and report the case.

FAMILY HISTORY.—Mrs. H. D. Father died at 76 of Bright's disease. Mother died at 59 with "some disease" of the liver causing dropsy. She had three brothers and three sisters. One brother had rheumatism and another varicose veins, but all three are living and reasonably healthy. Sisters are all dead. One died at the age of 39 years with gallstone, without operation; one at the age of 39 years with some throat trouble, probably cancer, and the third died at the age of 35 years with consumption. The sister who died with the throat trouble had at one time, several years previous to her death, an eruption of blebs on her face soon after being vaccinated, which was supposed to be a vaccinal eruption. Patient knows of no other skin disease in her family.

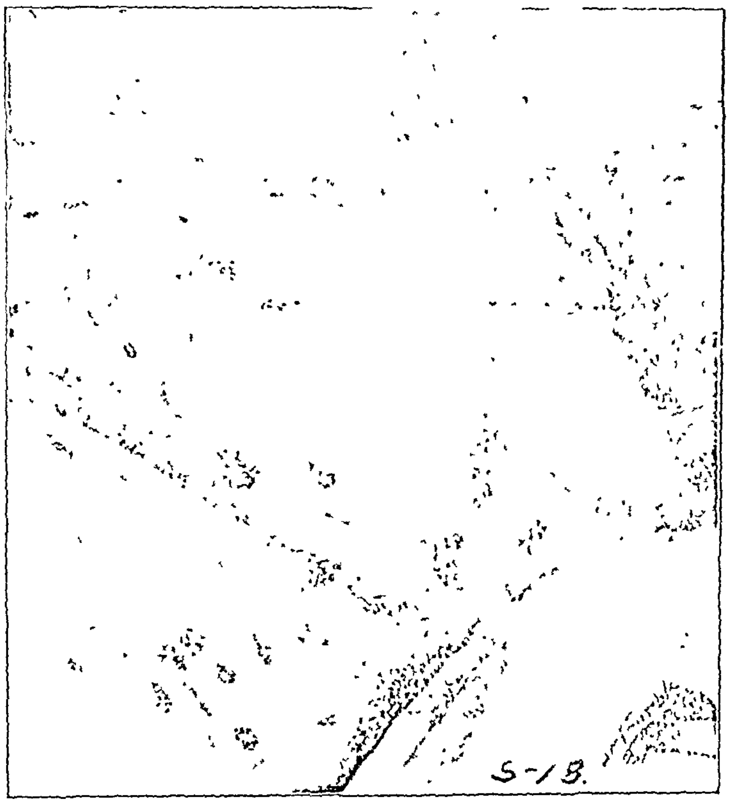

Fig. 2.—The eruption on breast and axilla.

PERSONAL HISTORY.—Patient is 53 years old and has been a widow for the last eight years. She is 5 feet 3 inches high, and previous to the menopause weighed 125 lbs. Since the change, which occurred seven years ago, she has increased in weight to 150 lbs. She is of the blond type, with decidedly nervous temperament. Says she always considered herself an entirely healthy woman previous to her present disease. She was born in Cromer, England, and came to America eighteen years ago. She was married at 29 years of age and had two children, the youngest of whom is now 21 years of age. She had a severe nervous shock eight years ago on account of the sudden death of her husband, and has been more nervous since. Thinks she has had more worry in the past two years than ever before.

HISTORY OF THE DISEASE.—The disease began a little more than two years ago on the mucous surfaces of the labia majora. Bullæ developed, varying in size from a pea to a pigeon egg. These came in crops lasting two or three weeks, after which they entirely disappeared for the same length of time, and then a fresh outbreak took place.

This manner of attack continued until early in June, 1892, when the eruption appeared on other parts of the body in about the following order: Inside the thighs, on legs, arms, breasts, abdomen, neck, outside the thighs, back of hands, feet, face, scalp, mucous membrane of mouth, and soles of feet. All parts of the skin were affected except the palms of the hands. A part of the time when the eruption was very profuse erythematous patches were observed covering considerable surfaces, but these seemed to have no influence on the bullous eruption. Blebs sprung up by the hundreds; sometimes on the erythematous patches, but quite as likely on normal appearing skin. They varied in size from a large pinhead to a hen egg, were superficially situated, and showed the greatest irregularity in *distribution and size*. It was interesting to see how quickly the largest attained their full size. Beginning with the pinhead size, they became as large as a hen's egg in six or eight hours. The most common size of the fully developed bleb was about that of the ordinary filbert, or, possibly, a little smaller. Some never became as large as a pea. Some stood alone, while others were grouped, but with no regularity of grouping. Every day fresh bullæ appeared, but no one could guess where they would appear the next day. One day the principal group might appear on the outer thigh, the next on the abdomen and the next on the foot. The largest of the bullæ developed on the inner side of the thighs. The blebs all stood out semi-globular, tensely filled with a clear, yellowish or straw-colored fluid, which became opaque within twenty-four hours if not ruptured. At the same time all stages can be seen from the beginning of the bleb to the pigmented spot after desquamation. The patient's appetite remained fair, and she appeared fairly well nourished, but rather pale. She complained of being weak and sleeping poorly. Bowels were inclined to sluggishness. Rigors and heat flashes were frequent, and the temperature ranged from 100 to 101 2/5 for a period of over two months. I saw her first on July 17. A urinary examination made July 20 showed: Amount passed in *twenty-four*

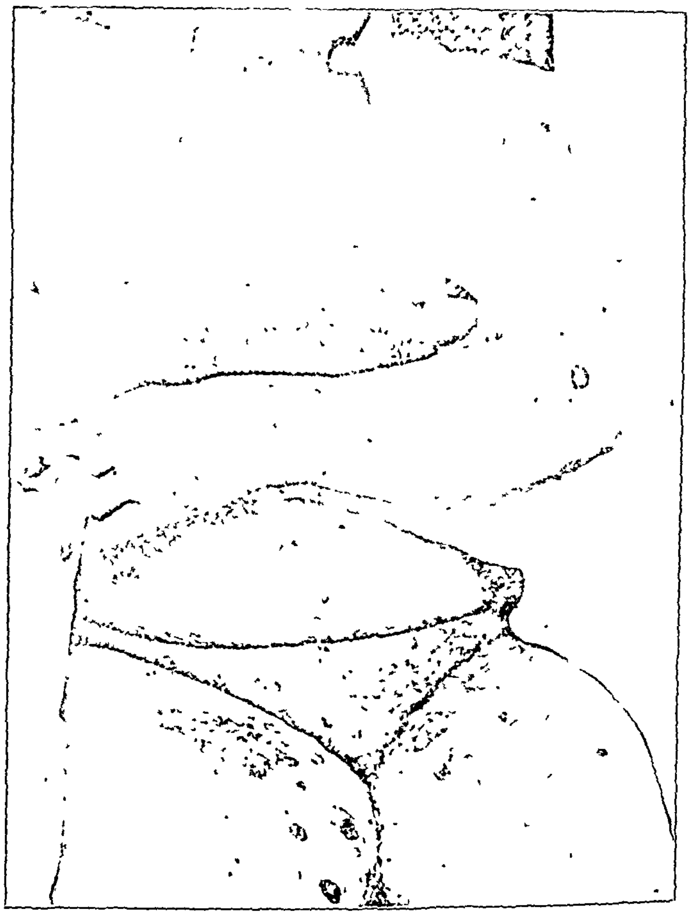

Fig 3.—Distribution of the eruption.

hours, 24 ounces; specific gravity, 1024; reaction, acid; slight amount of albumin, but no sugar; a few coarse granular casts, numerous flat epithelial cells and a few pus cells. This specimen was not taken with a catheter, and we concluded the pus cells and most of the epithelial cells were from the labiæ. Six weeks later another examination of urine, removed by the catheter, showed a normal urine and it still remains normal. All of the finger nails and the great toe nails were exfoliated, beginning about the middle of August, and were replaced by brittle, poorly-developed nails, full of longitudinal ridges. They grow slowly and break off at the free border.

BACTERIOLOGY.—A bacteriologic examination was made of the fluid in the blebs. Fresh, tensely filled blebs were selected and, with a sterilized hypodermic syringe, the clear fluid was withdrawn and thrown immediately into culture tubes. Four tubes were used, with a different culture medium in each. These were given in charge of Dr. E. L. Stewart at the laboratory of the Kansas City Medical College, whose report we give:

"*All the tubes showed a growth* of bacteria. These were plated out and examined. The bacteria isolated in pure culture are of two types, one a micrococcus and the other a bacillus. The micrococcus answers every description of the *Staphylococcus pyogenes albus* and seemed to be quite small. The other type—a bacillus in morphology—resembled very much the typhoid bacillus as seen on agar-agar culture except that it was smaller both in length and thickness and was not so mobile as Eberth's bacillus. It grew readily on agar-agar, gelatin, potato and bouillon, and maintained its mobility and morphology on all four cultures. On agar-agar it first appeared as minute white specks, later becoming confluent and evenly disseminated except at the border, where there seemed to be a slight elevation. In gelatin a stab culture gave a crater form liquefaction which proceeded with moderate rapidity. On potato the growth was not as rapid as on other cultures, but in forty-eight hours showed a smooth, glistening culture. It seemed to stain with carbol fuchsin better than with methylene blue and was decolorized by Gram's method. No experimental inoculations were made."

BLOOD EXAMINATION.—We did not succeed in getting a proper examination of the blood at the time the eruption was profuse. Such an examination was made in February, about six months after that stage had passed, but while a few blebs were present on different parts of the body. This examination showed a normal blood in every way.

We were unable to secure material for a histologic examination.

The period of profuse eruption continued from early in June till late in August, nearly three months. The last week in August the number of bullæ diminished rapidly and seemed to cease about September 1. For about two months there were none to be seen on the body, but on the mucous surface of the labia, which had been better during the three months mentioned, the same condition reappeared as before. It still continues, fresh blebs continually appear and soon break, leaving raw surfaces. This location seems never to be entirely free; on other parts of the body a few poorly-formed, superficial bullæ form, soon rupture and disappear. The patient has gained in strength and appears in nearly normal health in every other way.

TREATMENT.—The treatment of the case consisted in the use of nutritious foods, perfect rest in bed, removal of all excitement and worry, and the administration of tonics, especially arsenic. Quinin, iron and strychnia were also freely given. The treatment which gave the most comfort and seemed to do the most good was the antiseptic bath. It seems all observers agree that this is a valuable aid in treatment. Hebra and Kaposi report severe cases cured by means of the continuous bath. We were unable to secure such a bath, but used a simple warm water bath and also medicated or antiseptic baths (bichlorid and boracic acid). The simple bath did not seem to accomplish as much as the medicated. The bichlorid bath seemed to do more for the patient than any other kind. This was given as strong as 1 in 5000, the patient remaining in it fifteen minutes. This strength was not used daily for fear of getting too much absorption of mercury, but a weaker solution, 1 in 20,000, was used more frequently than the other.

We are not trying to prove the cause of this disease in this paper, but simply reporting our observations. It seems quite reasonable to me to conclude that the point of departure from health is in the nervous system and through this the skin manifestations take place.

THE TREATMENT OF EMPYEMA BY CONTINUOUS ASPIRATION.

WELLER VAN HOOK, M.D.
CHICAGO.

The disastrous results which sometimes follow simple open drainage of empyemas have induced a number of experimental and practical workers to undertake improved methods of treating such cases. These bad results consist in the failure of healing; in the formation of fistulas leading down to large cavities, often persisting for years after incision and drainage; osteomyelitis of ribs; retracting of connective tissue about the pleura, resulting in distortion of the thoracic viscera; infection with tubercle bacilli; secondary and remoter conditions such as amyloid degeneration and intercurrent diseases; and especially the distortions of the skeleton and the distant musculature due to the contraction and collapse of the chest walls. Most of these consequences are due to the mechanical conditions under which healing has to take place.

When the pleural cavity is widely opened the lung, on account of its elastic tissue, retracts immediately toward its root. During expiration there is a slight tendency on the part of the collapsed lung to expand, owing to the air from the injured lung being driven by expiratory pressure into the bronchus of the opposite side. During this temporary distension of the lung adhesion between parietal and visceral pleuræ can occur. The unfolding of the collapsed lung and the filling out of the pleural cavity take place partly by a progressive union between the parietal and visceral pleuræ due to the relief of tension at the point where granulations are most effective, during expiration (Roser).

Another cause of the closure of these cavities is to be found in the filling of the space by granulation tissue, while retraction of the new-formed scar tissue aids in drawing together the pleural surfaces, diminishing the size of the cavity. Relaxation of the diaphragm and the partial collapse of the chest wall, together with the adaptation brought about by the attendant scoliosis, give assistance in the process.

When cavities are very large interruption of any one of these processes may stop the progress of healing and the condition may persist for years.

Naturally the proper material to fill this space is the lung. To close the cavity by the alteration of the chest wall or by the pulling over of the mediastinal organs to meet the parietal pleura are makeshifts of but slight physiologic value. Obviously the correct procedure lies in the rapid closure of the cavity by inducing the lung at once to meet the parietal pleura, so that the pleural surfaces may quickly heal by granulation.

Several attempts have been made by different workers to overcome the pneumatic difficulties involved in these cases. Schede showed in 1890 that a common bandage could be made to act in a valvular way if it were made very large and put on very tight, and he has given us

He notes that in all recent cases the lung was distended (*entfaltet*) in a few days, "and yet the secretion diminished only gradually and the healing of the space (*spalte*) remaining after removal of the drain required a considerable time. This is only to be explained by assuming that a certain time was required until the pneumococci or streptococci imbedded in the superficial layers of the pleura died."

Perthes considers that his apparatus should be used when, four days having elapsed after incision, it is found that the lung has not resumed its contact with the parietal pleura. Of course, in many instances the tight dressing of Schede suffices.

In chronic empyema the necessity for the employment of this method of treatment is even greater than in acute cases. The second case observed by the writer convinced him of the value of the method under such circumstances.

Case 2.—George W., aged 6, entered Wesley Hospital Dec. 1, 1901. His previous health had been excellent. Seven weeks before, the parents stated, the child became ill rather suddenly and the family physician diagnosticated a pneumonia on the left side. Although the cough diminished, the patient did not improve much, and gradually the left side became more and more swollen.

On admission the patient was found to be a fairly well-developed child, but very much emaciated. He lay by preference on the right side and coughed a great deal.

Dulness on the left side extended from almost the level of the clavicle to the diaphragm, and from the spine to a point beyond the anterior median line. The heart was pushed well over to the right. The pulse ranged from 116 to 144; the respirations from 48 to 54. Marked bulging on the left side.

On account of the great embarrassment of the respiration and circulation the writer's usual practice of operating under local anesthesia was followed. At clinic an incision about one inch long was made in the anterior axillary line at the sixth interspace and an enormous quantity of pus escaped. Respiration became stormy and labored, until a large dressing was quickly applied. For several days the patient remained extremely weak, but, the temperature becoming nearly normal, improvement at last began and the cavity rapidly diminished in size. But when thirty lays had passed and the cavity had for a week held two ounces of fluid, it was decided to apply Perthes' apparatus to hasten the healing process. In five days the capacity of the cavity was diminished by half. The manometric pressure was raised from thirteen to twenty-five millimeters. Two days later, January 9, it was again increased to forty-seven millimeters; January 11, to fifty-three millimeters, and January 17 to seventy millimeters. After forty-eight hours the apparatus was removed and dry dressings applied. The sinus was a little slow to heal, but on January 26 was finally cicatrized.

The deformity was very slight and will, I think, eventually almost entirely disappear.

These cases are presented because the writer considers them suggestive rather than demonstrative, and because the original apparatus of Perthes' can be extemporized in the manner indicated.

The writer believes that a very important field of usefulness exists for continuous aspiration of the pleural cavity both in acute and chronic empyema.

103 State Street.

The Campaign Against Quackery.—To discourage poor persons who suffer from pulmonary affections from patronizing concerns which profess to have a cure for consumption, the tuberculosis committee of the New York Charity Organization Society has issued thousands of circulars to the poor. This was because a concern had attempted to link the name of the society with one of its advertisements in such a way as to cause the impression that the society indorsed the "cure."—*Pharmaceutical Era.*

UNILATERAL DISEASE OF THE KIDNEY SIMULATING STONE.*

JOSEPH RANSOHOFF, M.D., F.R.C.S.
Professor of Principles of Surgery, Medical College of Ohio, Medical Department of University of Cincinnati.
CINCINNATI.

When one considers the achievements in any field of surgery there is always one spot brighter than the rest by reason of especially good results; results obtained through faultless interpretation of symptoms and clinched by brilliant operation. In the field of renal surgery this applies to the operation for stone in the kidney, that is, when a stone is found. Unfortunately the elating thrill the surgeon expects to experience when the finger touches the stone in the opened kidney is not always felt; in its place is chagrin, if not discomfiture, when the fullest search fails to reveal the object sought for. To whom has it not occurred? A year ago the writer saw one of the foremost specialists in kidney surgery fail to find a stone in two cases within ten days. Were Tiffany to rewrite a paper presented before the American Surgical Association in 1889, he might readily present the reports of 200 cases instead of 21 in which the kidney was explored with results negative as to finding of a stone.

Two questions, necessarily correlated, at once arise, the solution of which would remove the obloquy attending a seemingly fruitless if not hazardous operation. They are: 1. Have we any positive and absolute method of recognizing stone in the kidney? 2. Are there not other pathologic conditions in the kidney, the symptom-complex of which covers to a nicety that of stone? In determining the first question in a positive sense the Roentgen ray was of necessity a formidable factor from the moment its penetrating power was known. With increasing experience in the methods of exposure, radiography will, in most instances, give positive results. There are few of the world's famous specialists who, like Leonard, are ready to make a negative diagnosis of kidney stone.

When I contemplate a few of the stones I have removed by operation, weighing 11, 15 and 20 grains respectively, some of them not larger than a pea, and removed from very fleshy individuals, I can not but believe that their discovery by the *x*-ray would have been largely a matter of chance. It goes almost without saying that an effort should be made to locate a stone by radiography in every suspicious case before operation. The sounding for kidney stone with a wax-covered ureteral bougie, as suggested by Kelly, seems to me chimerical in the extreme. To one conversant with the variations in position of a kidney stone it must be evident that its detection by sounding must be altogether fortuitous. Aside, then, from the positive presentment of a calculus by radiography the signs most relied on are pain, paroxysmal or continuous, and certain changes in the urine.

To consider the former at length is beyond the scope of this paper. Suffice it to say that the pain of stone may be simulated by any gross pathologic conditions of the kidney or ureter, such as tuberculosis, tumor, hydronephrosis, etc., and what is most relevant to the question propounded, by microscopic changes in the kidney, changes affecting either the secreting, the circulatory or supporting frame work and capsule of the gland. While ordinarily renal colic is associated with intrarenal retention from obstructed outflow, in certain chronic affections of the kidney with acute exacerbations the distension of a resisting capsule from within may be, and often does, give rise to a typical renal colic.

---

* Read before the Southern Surgical and Gynecological Association.

The most important factors making for a diagnosis of stone are obtained from an examination of the urine. Everyone associates hematuria with stone in the kidney. While this may be as profuse as in malignant tumors, it has, in my experience of nearly 20 cases, been marked rather by sparseness. In a paper[1] read before the American Medical Association in 1895, I insisted on the microscopic character and constancy of the hematuria as almost characteristic of stone in the kidney. The centrifuge alone will help us to distinguish a few, probably faded discs in nearly every sample of urine voided, and as long as pyelitis is absent a number of leucocytes proportioned to the discs as in normal blood. Albumin, except in traces, and casts, epithelial or blood, are not found ordinarily in the urine from a stone kidney, unless secondary nephritis has developed. The bleeding comes from the pelvis or its larger tributaries. During or after a renal colic the hematuria may be profuse. Its source is then not the pelvis alone, but the congested renal parenchyma, as it is in the hematuria from hydronephrotic kidneys.

In the urine of 1,997 persons examined by Musser blood was found by microscope in 364. All the cases of kidney stone had hematuria. "It is not an intermittent phenomenon, but one that is constantly persistent."

When we next consider that in certain but few cases of undoubted chronic nephritis albumin and casts are absent, often for months at a time and sometimes altogether, and that both pain and hematuria either microscopic or profuse may be present, it seems evident that the difficulties of differential diagnosis at times are insurmountable. True, in most cases of Bright's disease, hematuria is always microscopic; indeed, profuse hematuria has, until very recently, not been associated with this condition by clinicians. Naunyn's recent report of three cases has directed attention to the possibility of profuse hematuria accompanying Bright's disease.

With these difficulties of diagnosis before us it necessarily follows that cases must multiply in which a supposed stone is not found by operation or autopsy, and that many kidneys explored superficially by such inspection, as an operation permits, would be found seemingly normal. It also follows that explanations of the symptom-complex on some basis other than anatomic would be forthcoming. Because of the absence of such a basis it was natural that the pains should be designated neuralgic; surely an explanation that fails save in the rare cases of renal crises of locomotor ataxia, described as long ago as 1876 by Raynaud and Le-Reboullet, and distinctly allied to the gastric crises of Charcot. It remained for Sabatier, in 1889, to originate the euphonious term hematuric nephralgia to designate this group of symptoms; a term which defines concisely, but fails to explain. It is curious that in the Sabatier case he found a slight inflammation of the kidney, the importance of which in the production of symptoms he failed to recognize.

The same criticism of defining without explaining applies to the more recent terms of essential hematuria, angio-neurotic hematuria and renal hemophilia. But these terms are justifiably used when the non-existence of inflammatory or other changes in the kidney has been demonstrated by minute examination of post-operative specimens or by postmortems. How difficult this may be and how slight the changes, is illustrated by a kidney removed for essential hematuria and presented by Nickolish to the Paris Academy a year ago. In Vienna the kidney was pronounced normal. In Paris Albarran and Motz found marked evidences of glomerulonephritis. That profuse bleeding from the kidney can be a symptom of hemophilia, various forms of toxemia or arteriosclerosis without local changes in the kidney, is not to be questioned. It has also been noticed from normal kidneys after very prolonged exercises, notably horseback rides of many hours' duration. Barring these conditions, does it occur from normal kidneys? According to Schede, this only occurred in six cases, and Israel only concedes two, those of Schede and Klemperer, in evidence of its possibility.

A critical analysis of the conditions found when kidney stone or tuberculosis was fruitlessly sought, answers in the affirmative the second question propounded in the beginning of this paper, namely: Are there not other pathologic conditions of the kidney, the symptom-complex of which cover to a nicety that of stone? Such analysis, furthermore, enriches our knowledge of renal pathology by two important data. They are: First, that bilateral, chronic nephritis often manifests itself as an unilateral disease; and, second, that just as tuberculosis or infarct, though hemogenetic, may be unilateral, chronic interstitial, parenchymatous and capsular inflammation of the kidney may be limited to one side. Rayer already called attention to a case of this kind in his classical treatise on the kidney. Carefully studied cases of this nature are not numerous. This is my reason for presenting the following case:

History.—W. H. C.; aged 58; merchant. Family history negative in regard to patient's complaint. Father died at 56 of gangrene of the foot, mother died at 76 of pneumonia. One brother died at 60 of cancer of the stomach. Patient has always claimed to be of frail health. Had ordinary diseases of childhood. While in the voluntary navy had malaria. In 1884 had an attack of scarlet fever. After the attack of scarlet fever he became troubled with what was supposed to be cystitis, for which he was treated from time to time for ten years. In 1860 he had gonorrhea. About fourteen years ago he had his first attack of pain in the right loin and underneath the lower right ribs. This was associated with a sense of fulness and of soreness. He experienced at the time a sense of abdominal tension, which was relieved when vomiting set in. This was associated with an irresistible desire to urinate. Micturition was frequent and very painful. The attack lasted for several days, and was supposed to be appendicitis. The attacks first returned from time to time, and, to use the patient's language, then became more insistent and persistent. The patient has not been free from pain for a month at a time in the last ten years.

The case had been diagnosed at different times cystitis, appendicitis, pyelitis, stone in the kidney and floating kidney. When seen with Drs. Stewart and Forchheimer, the patient presented the following condition: Middle aged man of nervous temperament and ruddy complexion. Shows facial traces of severe suffering. He had been confined to his room for six weeks with pain in the right side of the loin reflected to the right groin. For the relief of this pain, the patient takes two to five grains of codein daily. During his confinement his temperature was always normal. When the attacks of pain are severest there is frequency of micturition. Micturition is painless. Never complains of pain in region of the left kidney.

Physical Examination.—This is negative except for some tenderness on deep pressure in the right costo-vertebral angle and over the right ureteral crossing over the pelvic brim. The kidney can not be palpated. Cystoscopic examination negative. Separation of the urines was not attempted.

Urinalysis.—While the patient was under observation fully fifty samples of urine were examined. At times there was a slight polyuria. The urine was always clear and limpid, free from albumin and casts. Every specimen examined when centrifuged, presented from five to ten red blood cells in the microscopic field. Often they were difficult to discern. Evidences of pyelitis were not found in the urine at any time. Hematuria was never manifest to the naked eye.

---

[1] The Journal A. M. A., July 6, 1895, p. 1.

Feeling nearly certain that the kidney harbored a stone, an *x*-ray picture was taken. Although it clearly revealed the kidney shadow, it showed no stone. An exploration of the kidney was nevertheless determined on.

Operation.—At Jewish Hospital, April 21, 1902. Oblique, lumbo-abdominal incision. When the deeper layers of the perirenal fat were reached, they were found much firmer than normal, and in exposing the capsule of the kidney firm adhesions to this of the fat layer had often to be divided with knife or scissors. The freeing of the kidney preliminary to incising it was as difficult as I have seen it after long-standing pyorenal fistulæ. The kidney, of about normal size, was very grayish in color and much firmer to the touch than normal. A stone could not be felt. After placing an elastic ligature in the usual way about the pedicle, the kidney was freely incised in the line first described by Hyrtl, and the pelvis opened. Except for possibly a slight dilatation of the latter, nothing abnormal was found. To the naked eye the kidney section appeared normal, except for a grayish color which may have been due to the operative ischemia. A thin section was removed for microscopic study. The ureter was easily probed to the bladder and found normal. The operation was terminated as an aseptic nephrolithotomy. This was perhaps a technical error, for a slight infection occurred which delayed recovery. The suppuration was extrarenal. In the course of this, a thrombosis of the left femoral vein supervened. June 5 the patient was discharged from the hospital well, except for a slight swelling of the left foot, the last sequel of the femoral thrombosis. This also disappeared. Since his return from his vacation the patient has followed his affairs; has had no pain of any kind, and repeated examinations of the urine fail to show any trace of hematuria. November 1 the patient reports a gain in weight of twenty-four pounds since the operation.

Pathology.—The following is the report of Dr. Hiller on the findings: The examination of the thin slice of kidney substance removed *intra vitam* reveals changes in the parenchymatous elements. Although the glomeruli have generally retained their normal appearance, here and there in areas the normal tingibility is lost, and distinct atrophy with granular change has occurred. The cells lining the tubules show in these areas a granular change with desquamation, the lumen of the tubule being often occupied by a granular debris in which nuclei are absent. On looking at the apparently normal kidney structure in the slide, the quantity of red blood cells both in and outside of the blood vessels stand out in bold relief. There is not present any distinct overgrowth of connective tissue nor are there any bands passing from the capsula propria of the kidney. This structure, although it does not appear thickened, seems unusually dense toward the outside.

In April, 1903, the patient reported from the Nile that he was in perfect health.

REMARKS.

The case presented is evidently one of atypical chronic inflammation of the kidney. In patches there was a distinct glomerulonephritis. From the adherence of the capsule proper to the fat capsule one might believe that a stone had existed at one time and was passed. The disappearance of the microscopic hematuria after the operation and the disappearance of all symptoms, and the fact that the patient never suffered from pain in the left kidney, make it reasonably certain that the disease in this case was unilateral.

Of considerable importance is the fact that a surgeon should not consider an operation on the kidney, in which he expects to find a stone negative in its results, when other changes in the kidney, as in the case reported, cover to a nicety the symptoms of stone. The capsule splitting and the section of the kidney will doubtless relieve many cases which simulate stone, and in which, because of the impossibility to make a positive diagnosis, are not now subjected to an exploratory operation.

In conclusion, the author would advise that in every case a small section of the kidney be removed for the purpose of microscopic examination. It is only in such a way that minute changes of the kidney can be discerned, changes which, although seemingly slight, are often capable of producing, as in the case reported, the severest symptoms.

ACUTE SUPPURATIVE CERVICAL ADENITIS OF INFANCY.*

THOMAS S. SOUTHWORTH, M.D.
Attending Physician, Nursery and Child's, Minturn and Randall's Island Hospitals; Physician, Out-Patient Department Babies' Hospital.
NEW YORK.

The condition to which I would direct your attention within the brief limits of this paper is by no means rare to those who have considerable clinical experience among children, and deserves to be qualified by the words "of infancy" inasmuch as the great majority of the cases occur in children under 2 years of age. At this period of life the lymphatic system is especially vulnerable and the lymph nodes in the cervical region particularly liable to infection and suppuration.

While in a few of the cases met, the infection of the gland has been preceded by and is traceable to some infected cutaneous lesion, in the vast majority of the most typical cases it seems evident that they are dependent on absorption from the nasopharyngeal space. The degree of inflammation in the nasopharynx seems to bear but little relation to the occurrence of the glandular swelling, many young children suffering from acute coryza or pharyngitis of considerable severity with slight or no enlargement of the cervical glands, while in others, presenting the type under consideration, it is rather the rule than otherwise that there is little or no nasal involvement at the time of the attack, although careful inquiry may elicit the history of an almost forgotten coryza a week or ten days previously. We are therefore led to infer that pathogenic germs have been carried to the glands and have there remained quiescent, or that areas persist in the nasopharynx from which by absorption a sudden glandular inflammation of considerable intensity may be lighted up.

It may be well for greater clearness to state that while those infectious diseases of childhood and the exanthemata which affect the mucosa of the nose and throat may often be accompanied by swellings of the cervical glands or even by suppuration, these are not at present under consideration, nor do they present the characteristic type and course of the acute cervical adenitis of infancy.

The usual history of the latter is that either with or without a known antecedent attack of influenza or coryza there is the sudden appearance of a marked swelling below the angle of the jaw, which, on examination, proves to be due to palpable enlargements of a lymph gland or glands lying somewhat deeply and obliquely from behind downwards and forwards just below the angle of the jaw and either chiefly anterior to or posterior to the sterno-cleido-mastoid muscle. The variation in the antero-posterior position of the mass appears to be due to the fact that there are two glands lying on about the same horizontal plane, one or both of which may be involved. The anterior one of these is easily palpated, the posterior one, which causes the swelling behind the sterno-cleido-mastoid, less easily, probably owing to its deeper position. Usually the chief incidence of the inflammation falls on but one of the glands, and the position of that one which is most enlarged determines the location of the mass. Holt in his text-book pictures the tumor as usually posterior. I have found it with about equal frequency anteriorly, and I present for your inspection two photographs of the same child in which evacuation and partial healing of the anterior gland was followed by typical involvement and suppuration posteriorly, which definitely confirmed my opinion that one or both of two glands might be involved.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

Despite these variations, however, the general appearance and situation of the swelling is so characteristic that the diagnosis can usually be made by inspection. The child's head is thrown towards the opposite shoulder and the usual hollow beneath the angle of the jaw is replaced by a prominent mass, one and a half to two inches long by an inch or more in depth. Fever is usually present, 101 to 103 degrees, with malaise and irritability, and the mass is more or less tender to the touch. Where resolution takes place the gland remains about the same size for some days, firm and easily movable, and then decreases in size more or less rapidly. If suppuration is to occur the definite outline of the gland is lost after some days in a brawny infiltration of the surrounding tissues and with considerable uniformity fluctuation is followed by pointing at about the end of the second week.

The careful clinical observer will not confuse this condition with the less definite external swelling caused by the dissection outwards of a post-pharyngeal abscess, which, if it have reached that degree, already gives its own characteristic clinical symptoms; nor with mumps, the swelling due to which surrounds the lobe of the ear and in young children extends but a short distance below the lobe—in fact, terminates at about the point at which the mass of an acute adenitis begins. The fact that tuberculous adenitis rarely occurs before the beginning of the fourth year, and that the progress of such glandular enlargement and suppuration is rather a matter of months than of days, should, but unfortunately does not always, prevent the mistaken diagnosis of that variety of infection.

To the parent any affection of the infant which calls for surgical interference with the knife is a source of anxiety and mental suffering, while cicatrices on visible portions of the body, such as the neck, are an especial source of regret. When suppuration has occurred with beginning fluctuation it is an important rule in the management of these cases to delay incision until the thoroughly softened mass points with redness, enabling us to choose for our incision a location where the skin only need be cut through to reach the purulent accumulation. This is occasionally considerably delayed, especially in deep-seated accumulations posterior to the sterno-cleido-mastoid muscle, but in the few cases where an earlier incision has been made without distinct pointing it has been evident that the glandular tissue had not fully broken down, and discharge from the abscess cavity was prolonged and healing was tediously protracted.

The general surgical rule to lay open freely any pus cavity for the purpose of securing adequate drainage has a notable exception in these cases of acute adenitis of infancy. Here the smallest incision which will allow of the evacuation of the pus and the introduction of the smallest obtainable drainage tubing is sufficient. If the mass is properly softened, as shown by pointing, the distended cavity contracts and granulation goes on with almost marvelous rapidity, granulations often pushing their way into the *fenestræ* of the tubing as early as the third day. Packing with gauze or the use of drainage wicks I have long since abandoned in favor of the tube, for the former is unnecessary, and both packing and wick become dry and adherent at the orifice, defeating our purpose by occlusion; favoring accumulation of pus and delaying restitution.

Since scars on the neck are to be regretted, especially in female infants, considerable attention has been given to securing the best cosmetic results by placing the smallest possible incision where it will be least noticeable. This is attained by placing the child in a bright light and seeking on or near the distended area of pointing for one of the delicate lines which mark what were the bottoms of the natural folds of the skin of the normal neck. On this line or, if it can not be traced over the mass, on a direct extension of this line, an incision is made without anesthesia but one-fourth of an inch in length. Evacuation of the pus is then favored by very gentle pressure and the occasional introduction of a grooved director or small dressing forceps until the cavity is entirely emptied. After slight stretching of the orifice with the dressing forceps a fenestrated tube three-sixteenths of an inch in diameter and one and one-fourth to one and a half inches long is introduced on a probe or small director to prevent doubling so as to reach the deepest portion of the cavity. This is secured externally with an 00 safety-pin, beneath which a fold or two of the dry dressing is, of course, placed to prevent uncomfortable pressure. On the second day usually the length of the tube is reduced one-half. On the third or fourth day there is but little discharge on the dressing and the tube may be removed. Thereafter there is a little thin mucoid discharge for a few days, and at the end of about eight days the wound is healed, leaving a minute scar at the bottom of a natural fold.

Where, after the removal of the tube, there is considerable induration of the tissues, the application of a 10 per cent. ichthyol ointment favors absorption and is more comfortable for the child than the dry dressing which becomes rough and hard with the drying discharge. When two adjacent glands have been involved and but one suppurated, induration is slow in disappearing. Rarely, as in the case of which I have shown you photographs, the adjacent gland suppurates later. If softening occurs rapidly we may occasionally reach the new cavity through the unhealed incision, but this is not often feasible. I have seen one case where it opened spontaneously on the seventh day into the unclosed sinus. Bilateral adenitis is not uncommon, but if one side suppurates the other usually resolves. My records, however, show cases where the other side suppurated from twenty days to six months later. Suppurative otitis media on the same side is a common sequela.

While strongly urging delay in incising until the appearance of localized pointing, this delay should not be prolonged until the skin is badly undermined, for in such neglected cases brought late to the surgeon healing is slow and unsatisfactory. This recommendation also should in no wise be construed to apply to the deep brawny phlegmon of the neck occurring in the course of scarlet fever where early incision is urgently indicated to prevent destruction of tissue if not of life.

Not all cases, however, of acute adenitis of infancy go on to suppuration. Holt states that in his experience of 109 cases, of which 96 were cervical, 62 per cent. suppurated. In my earlier experience with these cases certainly the majority of the glands broke down, but since the employment of the early and energetic abortive treatment, to be detailed below, suppuration has been the exception. Some years ago attempts to discover a successful abortive treatment were begun. Ichthyol ointment in various strengths was usually unavailing. Painting with iodin gave no better results. The continuous use of the cervical ice bag was ineffective. The various proprietary preparations of glycerin, kaolin and antiseptics in a mass of putty-like consistency, were faithfully tried, and only served to hasten suppuration like a poultice, for which purpose I now occasionally use them when abortive measures are clearly useless in the later stages. Absorption through the skin was evidently not sufficient in this region to affect the deep-lying glands.

The connection between chronic or subacute enlargement of the lymph nodes at the angle of the jaw and catarrhal conditions in the nasopharynx dependent on the presence of adenoid masses was then brought to my notice by the writing of Dr. Joseph Huber. The nasopharynx, owing perhaps to its situation and construction, has been accorded rather more than the usual neglect shown cavities whose interiors do not lend themselves easily to direct inspection. It seems to be only of comparatively recent date, despite the intimate connection between the condition of the mucosa of the nasopharynx and the integrity of the eustachian tube and the middle ear, that treatment of inflammations of the respiratory tract has been directed with any degree of regularity to this most resistant seat of catarrhal trouble, which, especially if adenoid masses are present with their deep sulci, affords an ideal opportunity for the retention and absorption of septic material. It is to Jacobi and Caillé that we owe, in this country most especially, the earnest recommendation of the nasal and post-nasal toilet for children, but only in the infectious diseases has this teaching taken root in general practice.

The connection between inflammatory conditions of the nasopharyngeal space and acute infections of the glands at the angle of the jaw once in mind it seemed probable that if promptly after the lighting up of the primary inflammation of the gland as evidenced by its enlargement, further absorption of infectious matter from the nasopharynx could be prevented, the gland might be able to cope successfully with the initial invasion and resolution occur, but that if fresh invasions were allowed to take place resistance would be overcome and the gland would break down. Attention was therefore at once directed to the problem of limiting septic absorption from the nasopharynx by measures which would keep the mucous membrane clean and also restore it as soon as possible to a normal condition. The plan adopted was as follows: When fever was present tablets were given containing:

℞. Tinct. aconiti
Tinct. belladon., āā..................m 1/4 | 016
Camphor..........................gr. 1/10 | 006

Sig.: One-half to one tablet, according to age, every two hours.

Chlorate of potash has an almost specific action in limiting the pharyngeal inflammations of childhood, therefore:

℞. Potassi chloratis...............gr. i to ii | 06-.12

Sig.: Every 2 hours for 24 hours, then every 3 hours, and later every 4 hours.

To cleanse and soothe the naso-pharynx:

℞. Tablets alkaline antiseptic (Seiler).

Sig.: Dissolve one in half glass water and pour a little with a teaspoon into each nostril every 3 hours.

The results obtained from the institution of this line of treatment were immediately most gratifying and a period of over one year during which these abortive measures were successful in producing resolution in every case would have been made rather too favorable a report to be credited. I have therefore withheld it until the series has been broken by a few failures (four in number) which under careful observation have in themselves proved most instructive.

A comparison of the series of cases, both without and with abortive treatment, shows in the latter a very marked reduction in the frequency of suppuration. In children over one year of age among whom under old method pus formation occurred frequently, there have been no failures. In infants under 1 year there have been but four failures, at 4, 5, 7 and 10 months of age respectively, in each of these temperature persisted and reached an average of 101 to 102 degrees each day.

1. The conclusions to be drawn from my experience are that: The abortive treatment of acute cervical adentitis of infancy as outlined is most promising, especially in children over 1 year of age.

2. The younger the infant the greater is the liability to suppuration.

3. A continuation of temperature makes the occurrence of suppuration probable.

807 Madison avenue.

DISCUSSION.

Dr. A. C. Cotton, Chicago—I believe it is my duty to go on record as approving this paper in the main. There is nothing especially new in the idea of the nasopharyngeal treatment of such cases, yet it is a matter of common observation that it is very rarely carried out. I think most practitioners of to-day will approve of a careful, judicious antiseptic cleansing of the nasal and post-nasal cavities. To be sure, there have been some objections on account of the possibility of forcing fluid, or rather infection, into the eustachian tube. With perhaps this single objection, I presume no one would differ from the essayist in regard to the importance of this nasopharyngeal and oral toilet. The determination of how much we believe in a thing may be best arrived at by observing our actions in regard to it. The Wisest Teacher said: "By their fruits ye shall know them." I recall a friendly review of a little publication that I brought out a few years ago, in which the book was treated in a most flattering manner, but the review closed with this statement: "The author's west side babies must be more tractable than those of the north and south sides, if they will permit the use of the tooth brush and atomizer advocated in this treatise." It was my privilege a year later to show the reviewer some families in which the daily systematic use of the tooth-brush, atomizer or nebulizer was as much a part of the toilet as the daily bath. The difficulties which to some physicians seem to be obstacles to the daily cleansing of the nasopharyngeal area are really insignificant. One father exclaimed: "Would you have me hold the child morning and evening while the mother and aunt perpetrate this cruelty?" It is needless to say that it had been improperly done. A little reflection will tell you that it is a simple matter if you approach the child on his weak side, and tell him he may have an atomizer for himself, such as papa and mamma have, provided he is specially good. You may use albolene at first; then some favorite perfume or flavoring, and finally you can use some disinfectant agent. Let me say that in the families in which I have succeeded in installing this nasal toilet during the past five years there has not been one case of suppurative adenitis. I think that prophylaxis lies along this line.

Dr. Charles Gilmore Kerley, New York City—I agree with Dr. Southworth regarding most of the statements made.

It is only necessary to make use of a small opening. Unless some means of drainage is employed, this small incision is very apt to close in twenty-four or forty-eight hours, and will then require reopening.

The point of differentiation between tubercular adenitis and simple acute adenitis might perhaps have been brought out more clearly. I understood the author to say that tubercular adenitis was not frequently found under the fourth year. I should modify this statement somewhat. I have seen quite a few cases of tubercular adenitis in children under four years of age; hence, this is not a sufficient ground for differentiation. I should lay stress on chronicity. In acute adenitis there is always more or less fever, and the swelling is more rapid, and one, two or perhaps three glands are involved; in other words, there is a distinct localization, whereas if the process is tubercular there is much more apt to be a distinct chain of affected glands extending sometimes down even to the clavicle.

The treatment of the nasopharynx is excellent. I am glad to hear chlorate of potash advocated, for I know of no better remedy for internal use. I have learned, in cases of acute tonsillar inflammation, to depend on chlorate of potash, and I believe that whatever good the old iron and chlorate of potash mixture did in diphtheria is to be attributed to the chlorate of potash it contained. The chance of infection of the eustachian tube in nasal cleansing I believe to be considerable, and I do not allow my students to make use of any force. The patient is placed on the back and the fluid is dropped in, or perhaps an atomizer is used. There can be no doubt that bacteria may be forced into the tube by the use of the syringe. Four or five years ago, in one of the hospitals for infectious diseases in New York City, nasal irrigation was used very extensively by means of the fountain syringe, and during this period the aurist was kept very busy treating disease of the ear. This only confirms my own experience. I prefer simple oil or albolene medicated as the case may require, and this should be sprayed or instilled and not injected into the nose. With regard to the abortive treatment, I have had good results from the application of a small ice bag kept constantly on the parts.

Dr. R. B. Gilbert, Louisville, Ky.—It is probable that the majority of cases of cervical adenitis do not come from the nasopharynx; most of the cases I see are the result of injuries and abrasions about the scalp. This is especially true in connection with invasion of the superficial glands, as from eczema. We often meet with cervical adenitis arising from caries of the teeth. I agree with the essayist, however, regarding the value of stimulating and cleansing applications to the nasopharynx. This should certainly be the routine measure. I can not quite agree with all that has been said regarding local applications, for I believe that fewer local applications, with possibly the exception of the ice bag, the better. Warm applications and ointments I think should be excluded. Iodid of potassium used internally certainly favors absorption, and I believe when administered every three hours in the full doses for the age of the patient, will accomplish more than any of the local applications mentioned, even more than the stimulating applications referred to. This treatment should be begun and carried out as promptly as possible in order to preclude surgical operation and unsightly scars.

Dr. Everett J. Brown, Decatur, Ill.—The reintroduction of chlorate of potash to the therapeutics of disease is to me very instructive. When I studied medicine the teachers warned us against the use of this drug, claiming that it produced profound anemia. My father, being an old practitioner, used to employ the old iron and chlorate of potash mixture, but I avoided it for the reason just mentioned. The patients, however, began to ask me why I did not prescribe the old mixture. I then began using it without the iron and I found that it was very valuable. In recent years chlorate of potash has been used very freely again, and has been recommended in very large doses in habitual abortion. For this class of cases I am now using it in divided doses of two and a half drams per day.

Dr. C. F. Wahrer, Fort Madison, Iowa—We have been told formerly by the best authorities that chlorate of potash caused a great deal of disturbance of the kidneys in young children. I believe we should not turn lightly from one position to the other in a Section like this, because its published opinions carry great weight. We can not afford to use forcible irrigations, and particularly with a substance like hydrogen dioxid. I have seen this substance employed in half strength in a child's nostril. The explosion of such a substance may do a great deal of harm by its action on the eustachian tube and middle ear, forcing infections beyond our control. The cleansing by such an agent should certainly be done only by instillation. The older practitioners looked on these cases of cervical adenitis as one of the evidences of scrofula, and while I am not quite sure what is meant by scrofula at the present time, I am of the opinion that it is generally tuberculous. However, we must be still careful about heroic medication with chlorate of potash and in the use of forcible irrigations in patients of tender age.

Dr. William Carver Williams, Chicago—Has the author of the paper had any experience with mixed infection in these glandular cases? I recently had a case of typical adenitis, such as he described, which was treated by the small incision at the stage of pointing. It refused to heal and there was considerable discharge at first. In time the whole chain became indurated, and exhibited the evidence of tubercular inflammation, and these glands eventually required removal by operation.

Dr. James G. Mastin, Chicago—I have been in the habit of using chlorate of potash internally in suppurative conditions and locally in sore throat. I believe this remedy will limit the formation of pus in a suppurative adenitis, and that if it is begun early enough we can almost wholly prevent the formation of abscesses. I think that chlorate of potash may be given without fear if the kidneys are in a healthy state. The use of irrigations by means of the fountain syringe, etc., and atomizers I look on as bad practice because it involves more or less force in the application of the remedy. For the past year I have been using Pattison's nasal irrigator, with which we can apply as much or as little force as we like. By applying the irrigator to one nostril a thin stream of water will flow out of the opposite nostril and by closing it with the fingers and holding the mouth open a thin stream of water will pass through the nasopharynx and out of the mouth, thus closing the nasal cavities and post-nasal space. I have not recently made use of albolene or other oily preparations, for, although they are good, I believe that normal salt solution is superior to them all.

Dr. H. N. Leavell, Louisville, Ky.—With regard to tonsillar involvement: Very often, if we will pull back the anterior pillar of the fauces, we shall find a little crypt full of cheesy matter which has not been sufficient to cause an acute tonsillitis but has produced enough irritation to involve the lymph channels. This, it appears to me, is an etiologic factor of some importance. With regard to the abortive treatment of these cases of cervical adenitis, I may say that I employed such methods very faithfully some years ago in the hope of avoiding suppuration, but like Dr. Southworth, I failed, and I believe there is not much gained by local applications to these glands. He is certainly reaching the cause of the trouble with his cleansing applications to the nasopharynx, but we must not lose sight of the fact that the eustachian tube is present in this region and is much more pervious than in the adult, so that the infectious material is more likely to be transmitted to the internal ear. This emphasizes the need of great caution against the employment of force. I agree with the last speaker regarding the use of saline solution. I believe it is better for cleansing purposes than anything else, and that it hastens resolution of the inflammatory process in the nasopharynx. It might be advisable to follow it up with the use of albolene sprays.

Dr. A. C. Cotton—I wish to explain what I have said. I did not refer to treatment but to the prophylaxis of cervical adenitis when speaking of the toilet of the nasopharynx. The albolene atomizer to which I had reference was the one which nebulizes the albolene, and it is deposited like a fog on the parts. Absolutely no force is used in the application, and the albolene goes wherever the air current goes. This oily material protects against crusts and the concealment of colonies of bacteria.

Dr. T. S. Southworth—I spoke in my paper about the employment of the spoon because it can be used without any force. The nose and throat specialists say a great deal about the danger of applications which we make to children's noses and throats, and yet they are in many cases employing compressed air sprays. I am of the opinion that if fluids are simply allowed to percolate through the nose and cleanse the mucous membrane, unless the nose is forcibly blown at this time no harm will result. It is the extension of the inflammation along the tube which I believe causes most of the trouble.

With regard to differential diagnosis of tubercular and ordinary cervical adenitis I would say that tubercular adenitis rarely occurs before the fourth year. While this is not an absolute point of differentiation it is, I think, a useful one. I am glad to hear that there is such a general use of chlorate of potash for pharyngeal and nasopharyngeal affections. I have always felt some anxiety with regard to the use of this remedy, although I prize it very highly. I have used it always very cautiously, yet it was only last summer that I learned from a medical friend of a fatal acute nephritis with hematuria in a girl of 17 from the use of chlorate of potash. The girl had purchased the tablets for a cold, and had eaten them very freely, with the result stated. Such cases should at least make us very cautious. The cases in which iodid of potassium proves serviceable in my experience are chiefly those in which there is a persistent induration, or in cases having a specific taint. I have not found it of so much service in acute cases. I have not made use of the chlorate of potash locally. It is quite possible that some of the cases which are very persistent are those in which there is a specific element, or perhaps a mixed infection. Here also the use of chlorate of potash has seemed to be of advantage.

THE ESTIMATION OF UREA BY MERCURIC NITRATE.

J. H. LONG.
CHICAGO.

Since the original publications of Liebig on the use of a solution of mercuric nitrate in the urea estimation several attempts have been made to so modify the process as to render it more perfectly accurate for the purpose. Liebig himself recognized the variable character of the precipitate formed when a solution of mercuric nitrate is added to one of urea, even when the latter has a mean concentration of 2 gm. to 100 c.c. and the mercuric solution is dilute, with 1 c.c. about equivalent to 10 mg. of urea.

This irregularity depends in part on the liberation of free nitric acid in the operation, and Rautenberg and others[1] attempted to correct for this by the gradual addition of alkali in the form of calcium carbonate. In this paper the authors recommend to correct the direct result of the titration by subtracting 0.06 c.c. of mercury solution for each cubic centimeter below 30 employed in titration of 15 c.c. of the prepared urine (that is 10 c.c. of urine and 5 c.c. of the usual baryta mixture). For example, if, in a given titration, 22 c.c. were used the correction to be subtracted from 22 c.c. is 8×0.06=0.48, leaving practically 21.5 c.c. to be used in the calculation.

Pfeiffer[2] later confirmed the value of the Rautenberg method as against the criticisms of Pflüger and others. Pflüger[3] published an elaborate investigation of the whole question and proposed a more delicate correction as well as certain definite methods in performing the operations of the test. His work is the basis of the processes described in many of our text-books.

Gradually, however, it began to be recognized that the mercury solution combines with several substances besides urea, and that it measures really, in a certain sense, the total nitrogen of the urine. This fact, coupled with the somewhat complicated procedure and corrections of Pflüger, led finally to the practical abandonment of this simple method in favor of others which are apparently more accurate. The various hypobromite processes can not, of course, be included here; their use is limited to the roughest kind of clinical applications. But I refer to the methods described by Pflüger and his followers on the one hand, and by Mörner and Sjöqvist on the other, for the separation of the disturbing factors from the urea before the actual test is made. A study of the literature, however, reveals the fact that in all of these methods and their modifications corrections are still necessary, and that, in general, they are not suitable for use when a rapid and fairly accurate process is required in making routine tests in urine investigations where the other important constituents are measured at the same time.

It is unquestionably true that in the mercury titration process the chief source of error is found in the volumes of solution required by the chlorids, the ammonia and the creatinin. The correction for the first may be easily made after the chlorin titration, and in fresh urine an approximate correction may be introduced for the ammonia and the creatinin, if they are not accurately determined. In a former investigation[4] I have made a large number of ammonia, creatinin and uric acid determinations and have found the correction to be introduced in the urea estimation on account of the presence of these. The mean value of the corrections are seen from these figures:

6 mg. of ammonia in 20 c.c. require 1 c.c. of mercury sol.
7.5 mg. of uric acid in 20 c.c. require 0.15 c.c. of mercury sol.
14.0 mg. of creatinin in 20 c.c. require 0.85 c.c. of mercury sol.

The 20 c.c. in each case is supposed to be made up of 10 c.c. of urine and 10 c.c. of water or baryta solution. In employing the process at all, or in the determination of ammonia, it is necessary to keep in mind that only fresh urine can be used with accuracy, because of the fact that in decomposition urea yields ammonia.

The apparently complicated corrections in the process as recommended by Pflüger are an objection to its practical use. I have, therefore, sought to simplify the procedure and corrections as far as possible, which may be accomplished in this way: First, the mercury solution is made in the usual manner and so adjusted that 20 c.c. correspond exactly to 200 mg. of urea in 20 c.c. when the end reaction is found as follows: Spread a number of drops of normal sodium carbonate solution (53 gm. Na_2CO_3 to the liter) on a glass plate with dark background, and as the end of the titration is neared bring a drop of the mixture in the beaker alongside one of the carbonate drops and cause the two to mix on one edge. Part of the beaker drop is thus drawn over the carbonate, giving a precipitate; as soon as this appears distinctly yellow consider the process finished and dilute the mercury solution so that exactly 20 c.c. should be required to produce this reaction, it being assumed that the standard solution in the beaker contained exactly 200 mg. of urea in 20 c.c. If a paste of sodium bicarbonate and water is used for the end reaction, or if the colored precipitate is obtained on mixing the drops by stirring, a different result will be reached. But if the final reaction is always made as just explained it will be found most satisfactory and readily observed. The actual urine titration must, of course, be made in the same manner, starting with a volume of 20 c.c. of prepared filtrate. Care must be taken to use pure urea for the standardization. That sold by dealers as pure may not contain over 90 per cent. of urea.

17.5	173.65	25.1	253.82	32.7	334.95		

With a mercury solution so adjusted I have made the following determinations. In each case a solution of urea in 20 c.c. of water was used and the end reaction was found as described. No neutralization was made, as part of the object of the experiments was to determine how to avoid this:

Urea in 20 c.c.	Hg sol. required.	Urea cor. to 1 c.c. of Hg solution.
100 mg.	10.45 c.c.	9.57 mg.
200 mg.	20.00 c.c.	10.00 mg.
300 mg.	29.47 c.c.	10.18 mg.
400 mg.	38.72 c.c.	10.33 mg.

The numbers in the second column are the means of many closely agreeing experiments. Those in the third column show the increase in the precipitating value of the mercuric solution. The value, y, of 1 c.c. of this solution for urea solutions containing from 1 to 4 gm. in 100 c.c. is given by the following interpolation formula derived from the observations:

$$y = 8.66 + 1.217x - 0.345x^2 + 0.03665x^3$$

By the aid of this formula and a curve drawn from the observations I have calculated the table given, in which the amounts of urea corresponding to different volumes of the mercury solution used are stated. The application of this table presupposes the use of a standard mercury solution, adjusted as explained above, and, further, that the titration is always made as recommended. The volume of mercury solution to be employed in the calculation is that which remains after subtracting from the total volume used the amounts used by the chlorids, uric acid, ammonia and creatinin, as shown in a short table above. In my own laboratory the method has been followed with excellent results.

In preparing urine for the test, I use 25 c.c. and mix with an equal volume of the usual baryta solution, accurately measured. The mixture is poured through a dry filter, and of the filtrate 20 c.c. is taken for the titration. This must be neutralized exactly with nitric acid, of which a drop or two is enough. Throw a bit of litmus paper into the filtered liquid and add the dilute nitric acid by means of a glass rod until neutrality is reached. The liquid is then ready for the mercury titration as described.

Northwestern University Medical School.

Personalities vs. Organization.—Every physician either is or is not honest and honorable and ethical, so far as the practice of his profession is concerned. If he is honest and honorable in his professional work, he should be a member of his local and state society; if he is not, he should not be permitted to join such societies nor to retain his membership in them if he has already joined. But no question other than professional integrity should be allowed to enter into the matter of medical society membership. Personal differences of opinion, envy, hatred or malice, likes or dislikes, nor race, school nor religion should so much as be thought of when the one great question of professional organization and of membership in the local and state medical societies is considered. If there must be squabbles, let them be outside; let medical organization be on the broadest possible lines, for professional honor and advancement, and for the benefit and protection of all honest and honorable professional men, no matter what their personal differences may be. Let us have a state society so big that personalities will be lost in it.—*California State Journal of Medicine.*

A Just Protest.—The *Medical World* of recent date contains a lengthy editorial instructing physicians how to extract teeth, describing the outfit needed, and urging them to take up the work. The article does not contain a word about what teeth should or should not be sacrificed. What would a physician think of a dental journal which advised dentists to perform amputations of various parts of the body, simply as a means of increasing their income?—*Dental Digest.*

THE CLINICAL SIGNIFICANCE OF ALBUMOSURIA.

Despite all modern methods of diagnosis the decision as to whether pus is or is not present, hidden in some unexplorable locality, continues to fret the diagnostician. The determination of the leucocyte count has not been as valuable as it promised to be, according to many, and at the best it is often inconclusive when a positive help is most needed. Any means that may assist in deciding this point is certain to attract attention, and we predict a general interest in the recent article of T. J. Yarrow, Jr.,[1] which considers the question of albumosuria as an aid in determining the presence or absence of suppuration, based as it is on extensive investigations by the author. Albumoses may get into the blood in a number of conditions, and even if only in small amounts they seem to enter the urine usually. The albumoses formed in normal digestion are ordinarily changed into something different while passing through the intestinal wall, but in case there is an area in which the intestinal epithelium is absent, as in ulcerative processes, they may pass into the blood unchanged and appear in the urine. The peptone that always accompanies the albumose in ordinary digestive processes seems to be more readily destroyed in the body than the albumose, for true peptone seems never to occur with the albumose in the urine. With the exception of this faulty intestinal absorption, albumoses are present in the urine only as a result of self-digestion of tissues in the body; conversely it may be said that whenever any considerable amount of dead tissue is undergoing softening at a fairly rapid rate, albumosuria may occur. Softening of dead tissues does not differ greatly from their digestion in the alimentary tract, for in each case similar proteolytic enzymes are producing similar splitting products, among which is the albumose. Although all tissues contain more or less active proteolytic substances, when softening is at all rapid it will be found that the leucocytes are taking a prominent part, not so much through phagocytosis and intracellular digestion, as we once thought, but more by extracellular digestion by enzymes that they liberate. Hence the rapidity of softening, and therewith the probability of albumosuria, will vary directly with the number of leucocytes attracted to the spot. For example, an aseptic infarct will soften much more slowly than a septic infarct, not chiefly because bacteria are present to destroy the dead tissue, but because the bacteria attract the leucocytes; similarly a tuberculous area is slowly or not at all absorbed because it does not attract leucocytes in any considerable number.

In view of these facts it is evident that albumosuria may occur under many and varied conditions, of which suppuration is but one, although the most prominent. For example, while the uterus is undergoing involution considerable quantities of albumose may be found in the urine, i. e., during the first three weeks after childbirth. Evidently, then, as with the leucocyte count, it is one thing to determine the existence of the symptom and another to draw proper conclusions. A simple method of detecting albumose is the first desideratum, and Yarrow recommends a solution of salicyl sulfonic acid, which produces with albumose a solution that clears up on heating; while the precipitate with other proteids becomes denser when heated. Again, it is important that a fresh specimen of urine be examined, since albuminous urines are soon digested by bacteria with production of albumoses. As a rule, the conditions that might cause albumosuria aside from suppuration can be excluded, and then the determination of this substance becomes of positive value. The instances of its usefulness are too familiar to need to be recalled, but, of course, appendicitis is prominent; here, Yarrow says, not only may the onset of suppuration be determined, but also the time of its safe encapsulation is indicated by the stoppage of absorption and elimination of albumose. If this is a general rule it will prove a great aid in determining the time of election for many sorts of operations. Another instance of the value of this symptom is seen in meningitis, for the tuberculous form will not produce albumosuria as does the suppurative. Resolution of pneumonic exudate, although entirely different from suppuration in its results, is chemically much the same as suppuration, and the albumosuria of resolving pneumonia has long been known. Of special interest to physiologists is the study by Yarrow of the urine of "over-feeders," for the failure to detect albumose indicates that the intestinal wall when normal can take care of all the albumose produced even with excessive diets.

It will be granted that albumose is not sought for in routine urinary examination by more than a very few, and since this symptom promises to be of value it is greatly to be hoped that Yarrow's work will lead others to study the occurrence of albumosuria, for in the matter of pathologic urine it is particularly true that only the accumulated results obtained in great numbers of cases by many investigators are of permanent value.

In passing we may mention the condition known as "Bence-Jones' albumosuria," about which a number of articles have been recently written, for it is to be distinguished from the true albumosuria of tissue disintegration. The Bence-Jones bodies, as the substance is more properly called, are not a true albumose at all, but, according to Simon,[2] it is more closely related to the water-soluble globulin. It is characterized by being coagulated by a relatively low heat, 58 C., as true albumose does not, and redissolving when heated higher, the precipitate again appearing when the urine is cooled down. Occurring as it does chiefly with the rare bone tumor, multiple myeloma, it seems to bear no relation to true albumosuria. Those interested in the subject are referred to the above article by Simon, and to articles by Bradshaw[3] and Boston,[4] where references to the literature will be found.

WHAT IS THE PROPER FUNCTION OF PUBLIC BOARDS OF HEALTH?

This question may well be raised at the present time, when it appears that health officials hold widely divergent views as to the proper scope of their activities. We take it that no physician will care to contend that the function of such boards is in any degree concerned with the health or well-being of any political party, although occasionally the solicitude of such a board for the success of the dominant party or its eagerness to oblige party leaders might suggest another view.

Setting aside, then, the always sinister influence of politics on the work of such a body, for what should a department of health stand? First, we must take for granted its strictly preventive functions. It must enforce vaccination and quarantines. It must abate nuisances. It must vigorously enforce the health laws and ordinances. But this is only a beginning. If it is the function of such a department to conserve the public health, then its scope and power must be constantly widened with the growth of the city, the development of the country and the growth of the science of sanitation. Nothing will compensate for the lack of a vigorous, fearless, scientific grappling with the difficult but immediate problems of public health and sanitation. It is to its board of health that a city should look for leadership, at least for co-operation, in the solution of the housing problem, for action in the prevention of tuberculosis, for fearless abatement of the nuisances created by certain great business concerns, such as glucose and rendering factories and various of the enterprises connected with abattoirs, for supervision of the health of school children and of the sanitary conditions in factories and stores where its citizens spend their working hours. Does this sound fanciful? It is merely a brief suggestion of the work of the New York Board of Health at the present day. If the board of health in any town lacks the power and equipment to carry out such a program its first duty is to make that fact known. If this is done in a manly and convincing manner there is no danger that popular response will fail.

Let us imagine, further, the value of a health campaign vigorously carried on by a state department of health. State universities employ teachers to travel over the state, to speak in every county on the health of cattle and the vigor of corn and the care of the soil. Why should not the state board of health send out teachers to speak on health and sanitation? If there were some popular knowledge of the premonitory symptoms of nervous breakdown our state insane asylums would soon feel the relief, and, in mere dollars and cents, the state would be repaid for its teaching.

City and state boards of health examine bacteriologic specimens for physicians free of charge. Why should not these boards also examine those conditions of water supply and sewage disposal, whose imperfections too frequently spread disease; why should they not distribute information in the remoter districts by means of lecturers and bulletins covering those simple precautions which would stay the spread of tuberculosis?

A public department of health should be not only an executive body administering laws and ordinances, making investigations, gathering and publishing reliable statistics, but it should be a great aggressive organ of popular education regarding personal and public hygiene, and all that pertains to public health and physical well-being.

THE PROTECTION OF THE BODY AGAINST ITS OWN DIGESTIVE FERMENTS.

Among the "old questions that are ever new" is the immortal problem: Why does not the stomach digest itself? A recent revival in interest is now evident; due to new observations along two lines, one of which is the demonstration of the presence of proteid-digesting enzymes in all the cells of the body, the other the direct study of "antiferments." Since it has been shown that all cells are capable of digesting themselves, after death of the tissue that contains them, the question naturally arose why they were not similarly digested during life. One of the popular solutions of the problem of the stomach and its failure to commit self-digestion was that the alkalinity of the blood in the walls of the stomach prevented the pepsin from acting on them, since it required an acid medium. But the fact that pancreatic trypsin acts best in alkaline medium rendered this explanation futile when applied to the conditions of self-preservation of the intestines, and the same thing applies to the autolytic ferments of the tissues. An ingenious method of attacking the problem lies in the ability of intestinal parasites to live in the active digestive fluids of the alimentary tract without suffering harm. That they are not impervious to the alimentary fluids is evident, since they obtain their nourishment by absorption from these fluids. As early as 1878 Fredericq observed that round worms from the dog's intestines could live for many days outside the body when kept in a solution of pancreatic juice. The early authors considered that the living tissues resisted the action of digestive ferments in the same way that they resisted the action of stains and of other substances, but this was more of a substitution of one problem by another than an explanation. E. Weinland found that not only do parasites resist the action of trypsin, but that they also rendered it incapable, to greater or less degree, of digesting other substances, and he thought tha sites protected themselves by producing an antibody for the ferment, an "antitrypsin." Dastre and Stassano[1] have followed the study of the defense of the tenia serrata of the dog still farther, and seem to have proved very nicely the method of protection. As has now become well established, the pancreatic juice as first secreted from the gland is usually quite inactive to proteids. Its proteid-digesting enzyme is in an inactive form, trypsinogen, and needs to be acted on by the intestinal juice before it is changed into the active trypsin, this change being accomplished by the enterokinase of the intestinal secretion. Dastre and Stassano found that if an extract of the tenia was permitted to act on enterokinase about four hours, the effect was that the enterokinase was unable to render fresh pancreatic juice active. On the other hand, if the tenia extract acted on fresh pancreatic juice, and this later was added to enterokinase, it became active almost as if untreated. Further, if the enterokinase and pancreatic juice were left to act on each other for a time and then treated with tenia extract digestion is active, although less than in the controls. Therefore, it seems that the tenia extract prevents the enterokinase from activating the trypsinogen, rather than interfering with tryptic action.

---

[3] Lancet, Oct. 4, 1902.
[4] Amer. Jour Med. Sci., October, 1902.

Fermi first showed that fresh blood serum not only was not digested by pancreatic juice, but that it attacked and destroyed its tryptic enzyme, an observation that has since been abundantly verified. Here again the action seems directed more against the enterokinase than against the trypsin. Delezenne[2] finds that serum not only checks enterokinase, but also the substances that occur in leucocytes, bacteria and venoms that have similar activating effects on trypsinogen. This power of normal serum to prevent the action of ferments seems to be quite as general as it is remarkable. For example, Simnitzky[3] finds that papain is similarly affected, and that the serum of animals immunized to certain bacteria is not only antagonistic to the proteolytic ferments of the specific bacteria, but also to similar ferments of other bacteria.

On the basis of these observations it would seem that the tissues do not digest themselves and each other because they contain something that prevents the action of the digestive ferments. But since it is shown that this antibody does not affect the ferment that has been made active, but is only effective against the kinase, being in fact an antikinase, it seems to us that the problem is quite as open as before, for in the alimentary tract the parasites and the intestinal walls come in contact with large quantities of active ferment. Jacoby's demonstration that the ferments of the tissues are specific for their native tissues also fails to explain why the tissues are able to digest themselves when they are dead, but not when alive, except on the assumption that during life the circulation restores the equilibrium as fast as the intracellular enzymes break it down. The leucocytes also show a great power to digest proteids of all sorts, not only themselves, but also the other tissues, and even foreign substances like catgut sutures, provided only that the proteid is dead proteid. It seems to us that so far the antiferments, interesting and important as they are, have failed to explain the riddle of the failure of self-digestion of the body by its own enzymes.

TO PREVENT ADULTERATED DRUGS.

It has been decided by the Attorney-General of New York that the State Board of Pharmacy has the right to take samples from drugs kept for sale by druggists to determine whether they are pure and of the quality established by the Pharmacopeia. There was evidently some opposition to this, but the recent publication of the Board of Health on the extent of cheating shows its necessity. It would be an excellent thing if similar bodies in other states exercised the same authority and carried it out in practice. The amount of damage done by adulterated drugs can only be imagined, but it must be a serious one in the light of such facts as were brought out in New York. Things are probably equally bad in other states and the remedy is just as applicable.

LIQUOR SELLING BY DRUGGISTS.

According to the *Western Druggist* the last New York legislature passed a law regarding the sale of liquor by druggists which permits its sale, without a physician's prescription, in quantities of less than one pint, with a state revenue stamp fixed to the package. As a preventive of too regular or too frequent sales, the provision is included that not more than one sale can be made to the same person in the same twenty-four hours. We do not know whether this law is a concession to the patrons or to the druggists. If the former, it is a fraud in prohibition communities, nullifying the will of people, and if the latter, it indicates a greater degeneracy of the pharmaceutical profession in New York than we like to think probable. The sole function of the druggist in the sale of liquor should be to provide it as medicine when prescribed by medical authority. If he is allowed to sell it to whoever asks, he is practically on the level of the dramshop keeper and nothing better. The sale of liquor should be under direct police regulations, and to permit it as an unguarded function of pharmacists destroys this essential feature. The New York law appears to us to be a distinct step backward and it ought to have the opposition of the licensed liquor sellers as well as the temperance public generally.

DEEDS OF DARKNESS.

Though Armstrong was duly sent up, not exactly in a chariot of fire, his mantle seems to have fallen on others, this time in the East. There exists at present, according to the *Baltimore News* of May 6, in that city a rather sacrilegiously named institution, the "Christ's Institution Medico-Chirurgical and Theological College," conducted by six colored men, an establishment which gives all sorts of degrees, and especially medical ones. When incorporated in 1900 it had only one M.D. among its organizers, and he signed his mark instead of his name. Now they all have M.D.'s, besides D.D., B.D., etc., *ad nauseam*. The man who could not sign his name in 1900 now appears as a Bachelor of Arts, Master of Arts, Bachelor of Divinity and Doctor of Philosophy. He is also professor of "linguistal," whatever that is. The degree of B.D. is given for $5 and a certain amount of study. Candidates for M.D. and D.D. apparently pay $50 per annum for their instruction. There is also a nurses' school attached to the concern that graduates its trained nurses. The establishment is in full blast and considerably patronized, not only by candidates for degrees, but by patients from the poor whites and colored people of the neighborhood. All this is almost directly under the shadow of the Johns Hopkins University It reminds one of the byway to sheol described by Bunyan under the walls of the celestial city.

HYDROPHOBIA.

We regret to see a regular medical journal indulging in sneers of "ignorant clamor" against hydrophobia. Hydrophobia is a reality, and a very serious one, and not all the sentiment or pseudo-benevolence of the zoophiles can disturb this fact. The destruction of all wandering dogs and all the pampered pets in our large communities would not compensate for the loss of a valuable human life destroyed through their agency. It is hard to see why a muzzling law can never be enforced; it has been enforced in Great Britain with the result of practically stamping out hydrophobia in that country. The editor of the monthly journal referred to remarks that the statistics of the New York Board of Health will probably show that perhaps two persons died of the infection from dog bites in four years. We can not dispute this from actual knowledge of the facts, but if statistics show that there were only two deaths from rabies in four years in New York, either the statistics are very far from being reliable or else New York has a much better record than other cities in this country. The fling at the New York Medical Association is unworthy. The Association is in much better business in agitating against hydrophobia than is the journal in belittling the importance of the disease and encouraging a false sense of security which may prove fatal to innocent individuals.

"DRUGS THAT ENSLAVE."

A short time ago we noticed some rather striking and alarming statements made in newspapers in regard to cocain addiction. Also in a recent number of the *Philadelphia Medical Journal* Dr. Simonton of Pittsburg gave an account of the spread of cocain under his observation. From the facts given by him, as well as those obtained elsewhere, it seems that the introduction of this drug to the public has been, and is likely to be still, a curse to the community. Its therapeutic advantages, and they are not slight, are hardly balanced by the evils that may come from its self-prescription. It is especially among the lowest classes that its use seems to be most general, though others are not exempt; Simonton speaks of even railway employes being victims to the habit. The negroes of the South, in the cities especially, seem to be becoming devotees of the cocain habit. The facts brought out would necessarily imply that certain druggists have been criminally active in making profit by spreading the sale of cocain. Some physicians have perhaps in the past thoughtlessly prescribed cocain in such a way that the patient has had it renewed and thus set up the habit. It is a matter that deserves the attention of the members of the medical profession, and they can not neglect it. Cocain is an attractive drug to prescribe, for its effects are so quick and decided, but it is, at the same time, one of the most dangerous tools we can use. Cocain addiction, however, is not the only vice that seems to be growing. In fact, a certain portion of the public seem bound to intoxicate themselves with almost every abomination that can produce a temporary effect. It is said that boys in some eastern cities have gotten into the habit of fuddling with gasoline, stealing it from suburban street lamps or from tank cars. In a recent case a boy in attempting this was blown up, the explosion injuring at the same time several others who were with him.

Medical News.

COLORADO.

Banquet to Dr. Tillmanns.—Dr. Henry Tillmanns, Leipsic, who is visiting America, was given a banquet at the Antler's Hotel, Colorado Springs, by Dr. B. P. Anderson of that city. A number of the profession were present, and toasts were responded to. The famous surgeon spoke in great appreciation of the reception extended to him in this country.

ILLINOIS.

Diseases at Bridewell.—Dr. Sceleth, physician at the Bridewell, Chicago, reports 82 patients in hospital, including 19 cases of pneumonia and 24 of delirium tremens.

New Trades Union.—Hospital attendants and nurses at the Cook County Institutions, Dunning, met, May 12, and organized a union with an initial membership of 160.

To Complete Hospitals.—The legislature has appropriated $200,000 for the completion of the hospital for the incurable insane at Bartonville, and $200,000 for improvements at the insane hospital at Watertown.

Personal.—Dr. and Mrs. William S. Pearce, Waukegan, celebrated their golden wedding anniversary, May 16.——Dr. and Mrs. H. H. Deming, Chicago, have returned after spending the winter in Cuba and Florida.——A banquet was tendered Dr. T. J. Bluthardt, Chicago, newly-appointed consul to Bonn, prior to his departure for his post of duty.——Dr. David M. Paulson, Chicago, sailed for Europe, May 15.

Osteopathy Bill Vetoed.—The governor has vetoed the bill which provided that:

> Licenses to practice osteopathy shall be granted by the state board of health to all applicants of good moral character who pass the regular examination of such board in anatomy, histology, physiology, obstetrics, gynecology, pathology, urinalysis, toxicology, hygiene and dietetics, diagnosis, theory and practice of osteopathy, and present to said board a diploma from a regular college of osteopathy maintaining the standard of the associated colleges of osteopathy in its requirements for matriculation and graduation, and requiring personal attendance for at least four terms of five months each.

Chicago.

Care for the Babies.—The department of health notes a decrease in the death rate last week among infants under one year of age, and considers it, in part at least, due to the urgent crusade now being made for pure milk. The department is circulating in seven languages directions for securing and recognizing good milk and caring for it before use.

Too Emphatic Statements.—Dr. T. S. Middleton, Chicago, who is given in Polk's directories as being both "R." and "H." and has having graduated at the Medico-Chirurgical College of Philadelphia in 1897; in the Illinois Medical Blue Book "Royal Coll., London; Wurzburg Univ.; Vienna Medic.; Chi., Phila., 1880. 1884, 1888," is evidently desirous of still more notoriety, as the following will show:

CHICAGO, May 26, 1903.

To T. S. Middleton, M.D.:—I have been reluctant to believe that you were correctly quoted in recent interviews published in some of the Chicago newspapers. But the report made to me yesterday by Dr. W. K. Jaques, director of the city laboratory, and corroborated by a reporter, leaves no room for further doubt that the interviews as published were substantially correct, or, as you said to Dr. Jaques on Friday evening, "all true and much more," implying that you had not told the worst.

Briefly summarized, and largely in your own language, your statements are as follows:

"Within the last month I lost twelve babies with something like marasmus. Then I began to analyze the milk and found formalin in every bit of it." "I found as much as three parts of formalin to ten of milk." "I use lime and blotting paper" in analyzing for formalin.

"There were nearly 125 deaths of milk fed infants and children on Wednesday of this week."

Each and every one of these sensational and mischievously alarming statements is absolutely and unqualifiedly false.

You have reported "within the last month" not one death of a baby to the bureau of vital statistics, as you are required to do by the state law and city ordinance with all deaths occurring in your practice. The only death you have reported since April 20 was that of a woman 77 years old, died on May 14.

You have failed to furnish any clew whatever to the identity of any one of these "twelve babies," although you promised to do so. Inquiry shows that you have not referred any one of these alleged deaths—due, as you assert, to formalin poisoning—to the coroner for investigation, as you are also required by the law to do in all cases of suspected poisoning.

You have not found "as much as three parts of formalin to ten of milk," and this mixture fed to one of your "twelve babies." In much less proportion formalin curdles milk and the formaldehyd gas given off would instantly strangle any person, baby or adult, who should try to swallow it.

You have never found formalin in any milk by your "lime and blotting paper" method. It is a chemical impossibility—an absurdity.

The standard and approved test for formalin is sulphuric acid, and in the thousands of examinations made for this agent by the laboratory it has never been found in greater proportion than one part of formalin to 10,000 parts of milk. And yet the test is so delicate and conclusive that it has been found in so small a proportion as 1 to 1,000,000 parts of milk, and the dealer was prosecuted and convicted on this evidence. "Lime and blotting paper," forsooth.

There were not "nearly 125 deaths of milk fed infants and children" last Wednesday, and you have no possible means of knowing on any given day how many deaths, even "nearly" there were on that day. The total deaths under 5 years of age for the whole week was 178—including those who died from convulsions, diarrheal diseases, diphtheria, measles, scarlet fever, and whooping cough. The highest number of deaths of infants and children under 5 years reported during the week was 43 on Monday, the 18th, but even the registrar of vital statistics could not know that until the following day.

In defense of the reputation of the city, which you have so recklessly assailed as one in which infant and child life is needlessly sacrificed; in justice to this department, whose working efficiency and morale have been impaired by your statements and others as baseless and mischievous; and in the interest of all honorable members of the medical profession—it becomes my duty to prefer charges against you before the State Board of Health for "unprofessional and dishonorable conduct," within the meaning and intent of the medical practice act, to the end that your license to practice medicine in the State of Illinois may be revoked. I am, sir,

Arthur R. Reynolds, M.D.,
Commissioner of Health.

KENTUCKY.

State Board of Health Officers.—On May 22 Dr. J. M. Mathews was re-elected president for two years; Dr. J. N. McCormack, secretary for four years; Dr. F. T. Eisenman, state veterinarian.

Cross-Border Troubles.—Dr. A. P. Hauss, New Albany, Ind., has protested against a decision of the Kentucky State Board of Health that he could not reside in New Albany and practice in Louisville, the ground for the refusal being the ruling of the Indiana State Board refusing residents of Kentucky a license to practice in Indiana, the language of the laws being identical in the two states.

Bad Water.—Secretary McCormack, in his report before the State Board of Health, referred in an exhaustive manner to the epidemics of smallpox in the state, the sources of the same, the difficulty of having many county courts pay the expenses of stamping out an epidemic, and the use of humanized virus in the country districts. Attention was called to the pollution of water supplies and a suggestion was made that the legislature be petitioned to pass stringent laws governing this question. A free examination of suspected water will be made by the state college if sent by a county board of health.

Sanitation in Railway Cars.—The annual meeting of the State Board of Health of Kentucky was held May 22 with a full attendance. President Mathews, in his report, referred to the necessity for action in regard to the sanitary condition of sleeping cars and day coaches. The report of the special committee on this question was heard, after which attorneys for the Pullman Car Company and the railroads asked for a hearing, which was granted. A special committee was then appointed to draw up regulations for the disinfection of cars to be referred to a called meeting of the board in June for final adoption.

MARYLAND.

The Biological Laboratory at Beaufort, S.C., will be under the directorship this year of Dr. Caswell Grave of Johns Hopkins. A large number of members of the graduate department of biology will spend the summer there in special research.

New Eastern Shore Hospital.—The cornerstone of the new hospital at Cambridge was laid May 26. The contract price is $35,000. Mr. John E. Hurst, a merchant of Baltimore, gave $25,000 of this. It is expected to be ready for patients by June 1, 1904. The present hospital is in two dwellings, and has fifteen or twenty beds.

Baltimore.

The deaths last week numbered 198, being an annual rate per 1,000 of 18.44 (white 16.03, colored 31.70). Consumption and pneumonia caused 24 and 18 deaths respectively.

Eastern Dispensary Staff.—The following were elected as the medical staff of the Eastern Dispensary, May 19: Dr. R. S. Kirk, superintendent, Drs. A. Hebb and A. L. Tumbleson, assistants.

The new staff of the Maryland General Hospital, connected with the Baltimore Medical College, consists of Dr. J. M. Delavett, resident physician, and Drs. W. G. F. Olmstead, A. W. Nelson, S. T. Cavins, E. G. Bray and H. M. Hutchins, assistants.

New Quarantine Building.—The board of estimates has appropriated $6,383 from the contingent fund for the erection of a detention barracks at quarantine. The building will accommodate 100 persons and will have four wards, one for each sex of each color.

The Charles Frick Research Fund has, by the beneficence of some citizens, been founded at the University of Maryland, the object being to found a memorial of this great investigator, who lost his most promising life forty-three years ago from diphtheria. It is an appropriate way to perpetuate his memory by reviving and perpetuating in the university where he gained his fame, those researches in diseases of the blood, urine and fevers which immortalized him a half century ago.

At St. Joseph's Hospital the resident surgeons for the next two years will be Dr. W. L. Burke, Baltimore Medical College, 1902, and Dr. W. E. Kurtz, University of Maryland, 1903. The resident physicians will be Dr. T. J. O'Donnell, University of Maryland, 1903, and Drs. J. A. Chatard and J. F. Fisher, both of Johns Hopkins, 1903. Of the old staff Dr. T. M. Green has gone to Wilmington, N. C.; Dr. Frank K. Boland to Atlanta, Ga.; Dr. W. E. Dolan to Boston, and Dr. H. J. Kearny to a New York hospital.

Personal.—Dr. Hector H. Goodman has returned from an extended tour through Europe and Palestine.——Dr. Charles H. Tilghman has been elected vice-president of the Queen Anne's Railroad Company.——Dr. Ira Remsen, president of Johns Hopkins University, was one of the speakers at the centennial of Justus Liebig's birth in New York, giving his personal reminiscences of the great chemist.——Dr. C. B. Farrar of the staff of the Sheppard and Enoch Pratt Hospital, has had his leave of absence extended so that he may continue his studies in physiologic psychology abroad. He has declined an appointment in one of the psychologic laboratories under the Carnegie fund.——Drs. Seymour D. Ludlam and Glanville G. Rusk, of the same institution, have been offered and have accepted positions, the former as assistant physician at the Friends' Asylum, Frankford, Pa., the latter as assistant in the laboratory of the New York State Hospital for the Insane, Ward's Island.——Drs. Franklin P. Mall and Warren H. Lewis sailed for Europe, May 25.——Dr. Jas. Bordley, Jr., sailed for Europe, May 30.

The graduating class at the University of Maryland School of Medicine number 96. The commencement was held May 19, Prof. Francis P. Venable of the University of North Carolina being the orator. The president of the class was Dr. A. L. Wilkinson. The prize winners were: First, Dr. Howard S. Holloway, Maryland; certificates of honor were given to Drs. J. Rosett, Maryland; G. C. Lockard, Maryland; E. H. Mullan, Maryland; F. C. Moor, Florida, and F. G. Wright, Virginia. Appointments were made as follows: Assistant resident physicians, University Hospital, Drs. H. S. Holloway, C. T. Young, and F. G. Wright; assistant resident surgeons, University Hospital, Drs. A. M. Shipley (reappointed), E. H. Mullan, W. Alstead and W. R. Hunter; assistant resident gynecologists, Drs. W. K. White, H. W. Brent and R. W. Fisher; resident pathologist, Dr. F. W. Weed. Drs. C. T. W. Sappington and J. H. Iglehart were appointed resident physicians at the

Maternity Hospital, and Dr. A. L. Wilkinson, assistant resident physician at Bayview Hospital.

MASSACHUSETTS.

Vaccination Suit Fails.—A suit brought against the town of Hyde Park by two children because they were excluded from school, through failure to comply with the school regulations in regard to vaccination, for $10,000 each, resulted in a disagreement of the jury.

The Children's Island Sanitarium, located in Salem Harbor, reports that during last season they cared for 229 sick children; 32 of whom had hip disease and 23 Pott's disease. Children from 2 to 10 years old are admitted and kept for several weeks. The season opens about June 1.

Bequests.—The Free Hospital for Women in Brookline receives $20,000 as a permanent fund for the general purposes of the hospital by the will of the late Robert C. Billings.——Dr. Edward de la Granja, who died May 11, left his entire property to the Massachusetts Maternity Foundling Hospital, including his private hospital in Shawmut avenue.

Boston.

Heat Causes Sickness.—The heat of the past week, while at no time reaching 90 F., produced several cases of sunstroke, most of whom were treated in the new City Hospital Relief Station.

One Smallpox Case.—The first case of smallpox to be reported in Boston for several weeks, has developed in a soldier stationed at Fort Strong, one of the harbor defenses, who had been in the city on leave of absence.

Quarterly Death Report.—Two thousand, nine hundred and eighty-two deaths were reported in Boston during the first quarter of the year, a rate of 20.07. Infectious diseases, except scarlet fever, were much less prevalent than last year.

The open-air gymnasium for women and girls at the Charlesbank, Boston, was reopened, May 15. Here, under a competent instructor, they have the same advantages offered in many places to men and boys. An enrolment of 200 working girls shows how the offer is appreciated.

Boston Death Report.—In spite of the heat, the reported deaths decreased to 196 for the week ending May 23, a rate of 17.43 per 1,000. Pneumonia was responsible for 26 of these; whooping cough, 5; heart disease, 15; bronchitis, 4; diphtheria, 6; scarlet fever, 4; typhoid fever, 3, and tuberculosis, 27. The number of children who died under one year was 30, and under five years 52, while of those over 60 there were 35.

The American Social Science Association devoted one day of its annual meeting to health topics. Dr. Samuel H. Durgin, chairman of the Boston Board of Health, presided. Dr. S. W. Abbot, secretary of the State Board of Health, spoke on "Possibilties of the Medical Examiner System"; Dr. Robert Amory on "Deaths Caused by Poison"; Dr. Edward M. Hartwell on "The Relation of Death Rates to Growth Rates"; Dr. Charles V. Chapin on "Preventive Medicine and Natural Selection."

MINNESOTA.

Osteopath Board Named.—Governor Van Sant has signed the bill regulating the practice of osteopathy and has named a state board of examiners.

Personal.—Dr. Burton J. Merrill, Stillwater, has been appointed a member of the State Board of Health, vice Dr. M. H. Reynolds, St. Anthony Park.——Dr. Ray Humiston, St. Paul, has been appointed police surgeon, vice Dr. Paul Cook, resigned.

Smallpox.—During March and April four deaths occurred from smallpox in St. Paul, and the health commissioner fears a further spread of the disease before summer.——Secretary Henry M. Bracken, of the State Board of Health, has issued a report of the smallpox conditions in the state for the week ended April 25, which shows a total of 107 cases as compared with 162 for the preceding week and 193 for the week previous. Hemorrhagic smallpox has appeared in Hibbing on the Masaba Range. One death has occurred, and it is reported that there are more than 20 cases in the town.

Medical Course Not Shortened.—Dr. Thomas G. Lee, Minneapolis, has sent the following communication to THE JOURNAL:

> Permit me to correct a statement made in THE JOURNAL, May 2, 1903. On page 1226 it is stated that the medical course at the University of Minnesota has been shortened. This is not the case. The length of school year has just been lengthened from eight and one-half months to nine months. The medical student must take four full years in the medical department. There has been recently established a six-year combination course leading to the degrees of B.A. and M.D. In this course a student takes the first two years in the academic department, then enters the medical department, and at the end of two years receives B.A. and two years later M.D. The present entrance requirement in the department of medicine is one year's academic work, and two years' academic work will be required for entrance in 1905.

MISSOURI.

Mudd's Will Filed.—The will of the late Dr. Henry T. Mudd, St. Louis, was recently filed for probate. The estate is valued at several hundred thousand dollars.

Dr. Bauduy Injured.—Dr. Jerome K. Bauduy, St. Louis, was seriously injured, May 13, by being run over by a wagon, whereby he sustained a concussion of the brain and other injuries.

Personal.—Dr. Herman L. Nietert retired from the superintendency of the City Hospital, St. Louis, which he had held for more than four years, and was succeeded by Dr. John Young Brown.

Many New Physicians.—On May 14 the medical department of Washington University, St. Louis, graduated a class of 53. The degrees were conferred by Chancellor W. S. Chaplin of the university and the venerable Dr. Elisha H. Gregory delivered the address to the graduates.

New Officers for Medical Colleges.—At the annual meeting of Central Medical College, St. Joseph, the following officers were elected: Dr. Thompson E. Potter, president; Dr. Chester A. Tygart, secretary; Dr. William T. Elam, treasurer, and Drs. O. Beverly Campbell, Hubbard Linley, M. F. Weymann and George C. Potter, directors.

NEW YORK.

Buffalo.

The Ewald Reception.—A reception was given to the members of the Buffalo Academy of Medicine by Dr. Charles G. Stockton at the Saturn Club, May 20, in honor of Professor Ewald of Berlin.

Deaths for the Month.—The April report for the department of health shows an annual death rate of 15.72 per 1,000. The principal causes of death were as follows: Pulmonary consumption, 51; typhoid fever, 13; pertussis, 6; diphtheria, 7; debility, 41; alcoholism, 5; cancer, 18; apoplexy, 14; meningitis, 16; arteriosclerosis, 7; valvular disease of the heart, 32; bronchitis, 16; pneumonia, 27; appendicitis, 4; nephritis, 18; violence, 41. Total deaths for April, 1903, were 498, as compared to 436 for 1902. From a bacteriologic point of view the Niagara River water was in fair condition.

New York City.

Foreign Surgeons in New York.—Prof. Hans Kehr, Halberstadt, Germany, was given a dinner in his honor by Dr. Willy Meyer. By the invitation of the same gentleman, Professor Kehr gave a clinic at the German Hospital. He was also invited by Dr. B. Farquhar Curtis to hold a clinic at Bellevue Hospital.——Professor Ewald of Berlin, Germany, read a paper before the German Medical Society, May 26. He is also expected to take part in the scientific program of the meeting of the Medical Society of the County of New York on June 3.

OHIO.

To Fill Chair of Physiology.—Dr. J. J. R. MacLeod, London, England, a graduate of Aberdeen in 1898, and at present demonstrator of physiology in London Hospital Medical College, has been appointed professor of physiology in the medical department of Western Reserve University, Cleveland.

Faculty Changes.—Several changes have been made in the faculties of Ohio Medical University, Columbus, Drs. Thomas G. Youmans and Darlington J. Snyder having resigned. Dr. Youmans will be succeeded by Dr. McKendree Smith. Drs. Ernest Scott, E. A. Hamilton, Scott Fulton and H. H. Snively were added to the medical faculty.

New Faculty Members.—Starling Medical College, Columbus, has made the following faculty appointments: Dr. Harvey W. Whitaker, professor of diseases of the nose and throat; Dr. Starling S. Wilcox, professor of genito-urinary diseases; Dr. William K. Rogers, professor of otology; Dr. John Dudley Dunham, professor of bacteriology; Dr. William D. Deuschle, professor of mental and nervous diseases; Dr. Charles B. Morrey, professor of physiology; Dr. Dickson L. Moore, professor of diseases of children; Dr. Earl M. Gilliam, associate professor of gynecology; Dr. Isaac B. Harris, lecturer on physical diagnosis.

Cincinnati.

Personal.—Drs. C. R. Holmes, A. B. Isham and Louis Schwab have been appointed medical directors of the Cincinnati Hospital.——Dr. Louis E. Cook has been appointed pathologist to the branch city hospital for tuberculosis.

The commencement exercises of the Medical College of Ohio were held May 2. Addresses were delivered by Drs. P. S. Connor and T. A. Reamy and by Prof. Howard Ayres, president of the university. The graduating class consisted of 53, a number of whom secured positions as internes to the various hospitals: Cincinnati Hospital, Dr. Harry E. Shilling, Troy, Ohio; Dr. Charles Goosman, Cincinnati; Dr. Alfred Vos, Cincinnati; Dr. Sidney, Cincinnati. To Christ's Hospital: Drs. Charles A. Langdale, Cincinnati; Dr. Gordon F. McKim, Burlington, Ky. To the Jewish Hospital: Dr. Charles E. Hauser, Cincinnati, and Dr. Frank P. Zerfass, Oxford, Ohio. To St. Mary's Hospital: Dr. Claude Youtsey, Newport, Ky., and Dr. Karl G. Zwick, Covington, Ky. To the Good Samaritan Hospital: Drs. Grear H. Baker and Merrick L. Bates, Cincinnati, and Dr. Robert Cofield, Bethel, Ind. To Speers Memorial Hospital, Dayton, Ky.: Dr. Walter C. Cook, Cincinnati. The commencement exercises of the Miami Medical College were held May 1, the college graduating a class of 40, one of the largest classes of recent years. Addresses were made by the dean, Dr. J. C. Oliver, and by the Rev. Dr. Davil Philipson. Interneships were secured by the following: Drs. Earl H. Bruns, Merle Flenner, H. H. Johnson, F. W. Krueger, Cincinnati Hospital; Dr. Park Gilmore, St. Mary's Hospital; Dr. J. H. Grossman, Marine Hospital; Drs. W. C. Williams and C. J. Harris, German Deaconess Hospital; Dr. A. J. Markley, Jewish Hospital. The meeting of the alumni of the Miami College was held on the evening of May 1 and some two hundred sat down to the banquet. Dr. Millikin of Hamilton acted as toastmaster, and addresses were made by Drs. Chapman of Toledo, Fackler and others. Dr. Joseph Ransohoff has been appointed under the new code trustee to the Cincinnati Hospital.

PENNSYLVANIA.

Chester Hospital has an anonymous donation of $2,000 for a sun parlor.

Pseudo Butter in Almshouse.—An agent for the Dairy and Food Department has discovered that the managers of the Williamsport Almshouse have been feeding oleomargine to the inmates. The maximum penalty is $1,000 fine and imprisonment. The managers are to be prosecuted.

Foreigners and Insane.—In his recent report to the board of managers of the Friends' Asylum for the Insane, at Frankford, the superintendent, Dr. Robert H. Chase, regards insanity to be on the increase. He considers that in the United States immigration is a potent factor in this increase; while only one-eighth of the population is foreign born, one-third of the insane belong to this class. The high pressure and rapid pace of living in densely populated centers is another potent factor ascribed to the results. A high value is set on the occupation of the insane in their treatment.

Report of Smallpox in the State.—At a meeting of the State Board of Health, May 23, the chief subject for consideration was smallpox, and its prevalence in certain localities. In the lumber camps about Cross Fork, Potter County, 75 cases of the disease are said to exist. The locality has been placed under strict quarantine, railway and postal communication being cut off. Dr. Benjamin Lee, secretary, reported that during March and April there were 1,416 cases of smallpox, with 61 deaths in Pennsylvania. Included in this number are: Philadelphia, 219 cases, 20 deaths; Pittsburg, 153 cases, 15 deaths; West Farfield township, Crawford County, 137 cases; St. Mary's, Elk County, 100 cases.

Philadelphia.

The new maternity and nurses' home of the West Philadelphia Hospital for Women, including four adjoining houses, was opened with a reception on April 28. By improvements which cost about $15,000 the hospital can accommodate 60 patients.

Physicians Dine.—On the evening of May 21 the celebrated Clover Club, of which Colonel A. K. McClure is president, gave a "doctor's dinner," at which the guests were chiefly prominent physicians, some fifty in number. Lieutenant-General Nelson A. Miles was one of the guests of honor.

Pennsylvania Hospital Annual Report.—At the recent annual meeting of the board of managers of the Pennsylvania Hospital it was reported that the expenditures during the past year were $135,185, which is $37,000 in excess of its income. During the year 40,701 patients received treatment.

Heat Strokes.—A period of excessive heat in Philadelphia and vicinity for the week ended May 23 resulted in a considerable number of cases of heat stroke. The temperature has rarely been so high in May; the maximum was reached on the 20th, the thermometer recording 92 degrees, making Philadelphia, for the day, the hottest city in the country.

Women Graduate.—May 20 the Woman's Medical College of Pennsylvania graduated 30. Dr. Ella B. Everett, professor of gynecology in the college, delivered an address on "The Future of Women in Medicine." General George M. Sternberg, surgeon-general of the U. S. Army, retired, gave an address on the "Newer Knowledge and Prophylaxis of Infectious Diseases."

To Inspect Foreign Hospitals.—Dr. Geo. W. Holden, Denver, Col., recently inspected the Henry Phipps Institute for the treatment of tuberculosis. Dr. Holden represents Lawrence Phipps, who recently gave $500,000 for the building and equipment of a hospital in Denver for the treatment of consumptives. Dr. Holden has gone abroad to study European hospitals for the treatment of tuberculosis.

Commencement.—May 23, at the commencement exercises of the Medico-Chirurgical College, 93 students were graduated in medicine. The orator of the occasion was Prof. Arthur E. Kennelly, Sc.D., of the department of electrical science of Harvard College. The previous evening the annual meeting of the alumni association was held, at which ex-Attorney-General John P. Elkin made an address. The annual banquet followed.

Hospital Appointments.—Dr. Mary W. Griscom has been appointed chief of the obstetrical staff of the Woman's Hospital. Associated with her are Dr. Elizabeth L. Peck, senior member of the staff of the West Philadelphia Hospital for Women, also a member of the staff of the Philadelphia Hospital, and Dr. Sarah H. Lockrey, elected to the vacancy caused by the retirement of Dr. Anna E. Broomall. The latter recently succeeded Dr. Ida Richardson as visiting physician to the West Philadelphia Hospital for Women.

Foreign Surgeons Hold Clinics.—Prof. Hans Kehr of Halberstadt, Germany, on his way to and fro to the Congress of American Physicians and Surgeons, held a number of clinics in Philadelphia, chiefly on the line of gall-bladder surgery. While in the city he was the guest of Dr. Max J. Stern of the Polyclinic, but was entertained by several of the prominent men of the profession. Prof. J. von Mikulicz-Radecki of Breslau held a clinic at Jefferson Hospital on May 16. A large number of the profession were present.

Cerebrospinal meningitis made its appearance at the League Island Navy Yard on April 1, since which time four of the apprentice sailors have died of the disease. There are said to be six sailors in the Hospital of the Naval Home suffering with the disease. The outbreak is believed to be due to the crowded condition on some of the receiving ships. The medical officials, including the chief medical inspector of Philadelphia, state that the disease is not "spotted fever," and that there is no cause for fear of the spread of the affection. Tents are being used to relieve the congestion of the vessels, and it is believed that the disease will soon be stamped out.

Health Education Campaign.—Dr. Edward Martin, the new director of the department of health, has announced his intention of conducting the department on educational lines. It is his purpose to ask the County Medical Society and the College of Physicians to aid in bettering the health conditions of the city, by taking up for discussion practical subjects such as preventive measures of disease. The source of typhoid fever infection, chiefly through the water supply, is emphasized. The Pediatric Society is asked to formulate regulations setting a standard for the milk supply, and to offer suggestions about infant feeding. Impure, unfiltered drinking water has been used in most of the public schools and the board of education has been asked for a report on the matter to the end that pure water may be supplied. The Pennsylvania Society for the Prevention of Tuberculosis has been asked to co-operate with the department in the warfare against tuberculosis. A plan is on foot to have the subjects of the latter disease who are inmates of the Philadelphia Hospital, to sleep in the open air, temporary provision for the same being made on the roof of the hospital.

Many Bequests.—By the will of the late Hiram Brooke, a retired dry-goods merchant of Philadelphia, $77,000 was bequeathed to charities. Among many bequests are the following: Philadelphia Dispensary, $500; Pennsylvania Hospital, $2,000; St. Joseph's Hospital, $1,000; Friends' Society for the Relief of the Sick, $2,000; Philadelphia Nurses' Home, $500; Insane Department of Pennsylvania Hospital, $1,000; St. Timothy's Hospital, $500; Home for Consumptives, Chestnut Hill, $500; Jewish Hospital, $1,000; German, Jefferson, Hahnemann and Episcopal hospitals, each $2,000; Bethany Dispensary, $2,000. Louis Rosenberg has given to the Jewish Hospital $5,000, to endow a bed in honor of his wife, and a like amount has been given by the sister and brothers of Herman Jonas, to found a bed in his memory. Nineteen hundred and sixteen subscribers to the Federation of Philadelphia Jewish Charities contributed $123,039.50 to the organization the past year. In the allotments made the Jewish Hospital Association received $30,000; the Jewish Maternity Association $9,000; the National Hospital for Consumptives, Denver, Col., $3,000. Among the bequests from the estate of Mary A. Allison were those of $2,500 to the Presbyterian Hospital, and $5,000 to the Methodist Hospital.

TENNESSEE.

Personal.—Dr. William Krauss announces that he is no longer connected with Memphis Hospital Medical College.

College Opens.—The medical department of the University of the South, Sewanee, opened for its eleventh year, May 7, with an initial registration of sixty.

Accident to Physician.—Dr. William Morrow, Nashville, was run over by a train recently, and his left hand was so badly crushed that amputation was necessary.

A Large Graduating Class.—A class of 195 was graduated, April 27, from Memphis Hospital Medical College. Dr. William B. Rogers, dean, delivered the faculty address; Colonel Carroll, president of the board, made the address to the graduating class, and conferred the degrees, and Dr. Rogers delivered the diplomas to the class.

GENERAL.

The Meningitis Outbreak.—Two additional cases of meningitis developed last week among the sailors at League Island Navy Yard. Most of the recruits are now encamped in tents, and no serious extension of the disease is feared.

Association of Medical Librarians.—The sixth annual meeting of this association was held in Brooklyn, N. Y., May 16, 1903. A number of librarians and physicians representing medical libraries throughout the country were present. Papers and discussions were contributed by Mr. C. P. Fisher of Philadelphia, Dr. T. G. Lee of Minneapolis, Mrs. G. W. Myers and Dr. E. H. Brigham of Boston, Mr. J. S. Brownne and Dr. W. S. Dennet of New York, Mr. A. T. Huntington of Brooklyn, and others. The officers elected for the ensuing year are: President, Dr. William Osler, Baltimore; vice-president, Dr. Abraham Jacobi, New York; secretary, Mr. Albert T. Huntington, Brooklyn, and treasurer, Dr. George D. Hersey, Providence.

FOREIGN.

Serum Diagnosis of Meat Poisoning or Botulismus.—The German war department has issued orders that in case of suspected poisoning from meat the serum test shall be applied, as it has been found that the serum of persons convalescing from botulismus has marked agglutinating properties for the enteritis bacteria. The results of this test may enable a retrospective diagnosis to be made, even several days after recovery.

Pribram's Jubilee.—The thirtieth professional anniversary of Professor A. Pribram was celebrated May 14 at Prague, with much ceremony. The *Prager Med. Wochft.* of that date contains the complete list of the scientific works of this eminent savant and those of his pupils, filling several pages. Three numbers of the *Deutsches Archiv f. klin. Med.*, vol. 74, formed a jubilee number in his honor, the articles all emanating from his clinic.

Jubilee for Professor Runeberg.—The *Zeitschrift f. klin. Medicin* has issued a Festschrift in honor of Professor J. W. Runeberg, who has completed his twenty-fifth year in the chair of clinical medicine at Helsingfors. Twenty original articles were contributed by his present or former pupils. We notice that one of the prominent pictures at this year's Salon at Paris is a portrait by a Finnish artist of Runeberg in his apron at the bedside of a hospital patient.

Medical Study Trip in Germany.—The third annual study trip of physicians to the watering places of Germany from Kreuznach, Ems, Nauheim, Wildungen and Oeynhausen, etc., to Pyrmont, commences at Mayence, September 8, and terminates at Cassel the day before the opening of the Naturforscher Congress there September 20. The first stage of the journey will be by steamer on the Rhine. These study trips are becoming more and more popular every year, and the party receives almost an ovation at each health resort visited.

Campaign Against Yellow Fever in Brazil.—According to an official announcement by the Brazil Board of Health, disinfection will no longer be enforced in cases of yellow fever. As it has been established that the mosquito is the only means of transmission of the disease, prophylaxis will be restricted to isolating the patient, in his own house, if desired, screening doors and windows and using pyrethrum, formol and other insecticides in the house and in those adjacent. Physicians are urged to report all cases on suspicion, without waiting for a positive diagnosis, and the lay press, as the guide of national opinion, is entreated to uphold the authorities in this campaign on new lines.

Campaign Against Quacks in France.—De Lavarenne has been publishing in the *Presse Médicale* a series of articles urging concerted and vigorous action against the ads of charlatans, and emphasizing the harm done by them both to the public and medical profession. The matter has been taken up by Dr. Maxwell, who is attorney general for the Bordeaux Court of Appeals, while he is at the same time a physician. He is collecting material for a medicolegal study of the subject, and appeals to the profession at large for data. He wishes to have samples of particularly flagrant ads forwarded to him, and also all information of injury done by the quack practices or by the delay imposed and of excessive charges.

The Outlook for the Consumptive.—Lutaud protests editorially in his *Journal de Méd. de Paris* against the exclusion of tuberculous subjects from various occupations, which is being advocated in France. He thinks that the campaign against tuberculosis is becoming more and more "war on the tuberculous." If the state closes all avenues of employment for them, official clerkships, positions as teachers, etc., then, he argues, the state must either kill them off or else support them. If the latter, the state will in time be besieged by troops of impostors simulating tuberculosis to be supported without work. Lutaud has never accepted the prevailing bacteriology and exclaims in conclusion: "Oh Theory, Theory, how many stupid things are done in thy name!"

The Contract Practice Troubles in Germany.—The Reichstag has modified the sickness insurance legislation, as anticipated, to increase the maximum period of support from thirteen to twenty-six weeks, and in maternity cases from four to six weeks, and also to include the venereal diseases in its provisions. The new law does not mention the question of remuneration of the physicians, but five of the deputies, representing all the political parties except the socialists, delivered able speeches on the exploitation of the medical profession by the sick benefit societies, and other matters affecting the relations between the profession and the "Kassen," calling on the government to interfere to prevent the degradation of the medical profession. One exchange remarks that the subject could not have been presented better or more convincingly by any medical man, and this unprecedented pleading on behalf of the profession is accepted as a very gratifying sign. The Reichstag in consequence adopted a resolution before it dissolved commending the matter to the action of the next parliament, suggesting the appointment of a standing committee of representatives of the medical and lay officers of the "Kassen."

International Congresses in Europe.—The third International Congress of Thalassotherapy (marine) met at Biarritz, April 19 to 21, with a numerous attendance. Addresses were made by Liebreich, Berlin; Winternitz, Vienna, and Robin, Paris. The International Antialcohol Congress convened at Bremen just before, and the second International Congress of the Medical Press followed at Madrid, preceding the great International Medical Congress. The third International Congress of Public Assistance and Private Benevolence will meet at Bordeaux, June 1 to 7, and the seventh of otology at Bordeaux August 1 to 4. Beside these the German Otologic Congress assembled at Wiesbaden May 29; the German Congress of Surgery will be held at Berlin, June 2, and of orthopedic surgery at the same time, while the gynecologic will be held at Würzburg; August 1 is the date for the third French Congress of Neurology. The eleventh International Congress of Hygiene and Demography is announced for September 2 to 8 at Brussels. September 16 to 19 the German Public Health Congress will meet at Dresden, and September 20 to 26, the seventy-fifth Naturforscher Congress at Cassel.

Second International Congress of the Medical Press.—The constitution outlined at the Monaco conference was definitely accepted at this congress, which immediately preceded the International Medical Congress at Madrid. Dr. Cortezo of Madrid was elected president of the international association, and his journal, "El Siglo Medico," will, therefore, be the official organ of the international medical press until the next congress. He is an accomplished linguist and addressed the assembly in four languages, turning to the French, German, Italian and Spanish members as he spoke in their tongue. It was stated that there are at present 1,183 medical periodicals in the world, this country leading with 258, followed by France with 237, Germany with 163, Italy with 109, England with 77, Austria with 73, and Spain with 70. Russia has 47, Belgium 28, Holland 23, Argentina 11, and so on to Venezuela with one. Among the addresses made at the congress was one by Blondel, Paris, on the necessity for establishing an international central bureau for medical journals similar to that of the Associated Press for daily papers. Others spoke on the influence of the medical press on the decrease in the mortality from diphtheria. Rodriguez-Mendez discussed the subject of the education of the medical journalist. Noguera expatiated on the influence of the medical press on the progress of military science, and Pulido on the relations of the medical press to the public authorities. Interesting historical sketches of the medical press in various countries were read by delegates. The members of the congress assembled in a banquet after the congress adjourned.

International Anti-tuberculosis Conference at Paris.—The second and final sitting of the inner council of the international bureau for the prevention of tuberculosis, was held at Paris, May 3. The first conference met at Berlin and we all remember the heartiness with which the German government threw open its national halls for the conference and promoted it in every way. At Paris, on the other hand, the public authorities were too engrossed with the reception of the king of England and other matters to officially co-operate, so the entire arrangements devolved on private initiative. Letulle is secretary-general to the International Antituberculosis Congress to be held at Paris in October, 1904, and welcomed the members of the inner council at a reception at his house, where some unpublished poems of Professor Richet were recited or sung by professionals. The council accomplished its task, which was the gathering and comparing of information in regard to the campaign against tuberculosis in various countries, as a preliminary for the work of the approaching congress. The assembly concluded with a grand meeting thrown open to the public, the hall crowded to the doors, eliciting great enthusiasm. Casimir-Perier in his address at this meeting urged the co-operation of hygiene to arrest the progress of tuberculosis, with state aid, which deprives it of victims. These two are indispensable and inseparable. Both should act with gentleness and not with brute force. Their success, he added, is bound up with the solution of the most complex social problems and the campaign against tuberculosis should not be left to the medical profession alone, but requires the mobilization of all the forces of society, public and private, official and voluntary. A subcommittee was appointed to confer with local and national authorities in regard to measures to control the spitting nuisance. A resolution was adopted urging that the laws governing the spread of infectious diseases, especially tuberculosis, should be taught in schools and colleges.

LONDON LETTER.

Increase of Lunacy in Scotland.

From the report just issued it appears that the number of insane in the asylums of Scotland is 16,658. The statistics from the year 1858 onward show an increase. In that year the number was 5,824. The proportion of insane to the population has been steadily rising in the last ten years. In 1893 it was 204 per 100,000; now it is 250.

The Sleeping Sickness in Uganda.

Dr. C. Christy of the Liverpool School of Tropical Medicine and one of the commission dispatched to Uganda by the Foreign Office and Royal Society to investigate sleeping sickness, which is ravaging that country, has just returned to England. He made a very interesting journey among many little known tribes, returning via Fashoda and Khartoum. His special object was to prove or disprove the theory that sleeping sickness depends on filaria in the blood stream. After three months traveling he found a large district in which sleeping sickness raged and there was no sign of filariæ. It is now proved that sleeping sickness is in no way connected with filariæ. Simultaneously Dr. Castellani, bacteriologist of the commission, was working in his laboratory at Entebbe. He has proved that sleeping sickness is due to a previously unknown bacillus. Meanwhile the disease is making great ravages through South Kavirondo and along the shores of Victoria Nyanza. In villages through which Dr. Christy passed half or two-thirds of the people were suffering from sleeping sickness. A satisfactory feature with regard to Uganda is that the disease shows no tendency to spread far from the shores of Victoria Nyanza. It is not infectious in the ordinary sense of the word, and seems seldom to be conveyed from one person to another.

The King's Sanatorium.

As announced in The Journal, Sir Ernest Cassel, a wealthy merchant, placed at the disposal of the king about a year ago the sum of $1,000,000 for some purpose of public utility. The king decided to build a sanatorium for consumption. Prizes were offered for the best essays and plans for such an institution. Of 180 essays sent in Dr. A. Latham gained the first prize of $2,500. A sanatorium will be built according to his plans at what Sir William Broadbent describes as "a perfect natural site" in Sussex, near Midhurst. It is near a vast open space called Pound Common, which is public property, and, therefore, safe from the encroachments of the builder. For miles around are breezy stretches of gorse and heather. To the north of the site is a solid screen of the plateau itself, and on the east and west are acres of trees. The aspect of the sanatorium will not be absolutely south, for Dr. Latham has pointed out that it is not desirable in summer, when the sun would pour directly into the patient's rooms to make them uncomfortably hot. A slight inclination to the east or west will, therefore, be adopted. The extent of the property to be laid out is 151 acres. A fine garden will be laid out around the building. It is the ambition of the king that this should be the most perfect sanatorium for consumption in the world, embodying the experience of all the best models.

The Action on Bacteria of Electrical Discharges of High Potential and Rapid Frequency.

At a meeting of the Pathological Society Mr. Alexander G. R. Foulerton and Dr. A. M. Kellas read an interesting paper on this subject, in continuance of a communication on the same subject presented to the society last year, showing that by discharging the current close to the surface of a fluid containing bacteria, held in a test-tube, through the bottom of which a platinum wire had been sealed, suspended organisms could be destroyed. The current used was one of from 2.5 to 5 ampères, the voltage varied from 35 down to 24, and the experiments were carried out in common air.

The Plague.

In Cape Colony the following cases are reported for the week ending April 18: Quarantine station, Saldanha Bay, 2 Asiatics; Port Elizabeth 7, of whom 6 were natives and 1 European. Of the former 3 were found dead; at the plague hospital, Port Elizabeth, there are 17 cases under treatment. Plague-infected rats continue to be found in the town

Deaths from Violence in London.

Sixty-five deaths from violence occurred in the week ending April 25; 13 were suicide and 2 homicide, while the remaining 50 were attributed to accident or negligence.

Infectious Diseases in London.

In the London fever hospitals there are now 38 cases of smallpox, 1,698 of scarlet fever, 767 of diphtheria, 10 of typhus, and 60 of enteric fever. The admissions during the week as compared with the preceding three weeks are as follows: Smallpox, 9 cases against 3, 5 and 22; scarlet fever, 243, against 205, 158 and 188; diphtheria, 108, against 136, 99, and 96; enteric fever, 4, against 15, 8 and 5. During the four weeks ending April 25 the total death-rate for the metropolis was 16 per 1,000, being 3.3 below the mean rate in the corresponding periods of 10 years, 1893-1902. In the week ending April 25 there were 1,483 deaths, which included 80 from measles, 7 from scarlet fever, 22 from diphtheria, 33 from whooping cough, 17 from diarrhea, and not one from smallpox, typhus or enteric fever. The deaths from measles, which had been 73, 48 and 74 in the preceeding three weeks, rose to 22, but were 11 below the average. The deaths from whooping cough, which had been 60, 47 and 33 in the preceding three weeks, rose to 38, but were 22 below the average. Twelve deaths were attributed to influenza against 17, 17 and 8 in the preceding three weeks.

Correspondence.

Illinois Nurses' Bill Vetoed.

CHICAGO, May 26, 1903.

To the Editor:—An editorial bearing the above caption appeared in THE JOURNAL, May 16. As the information therein is incorrect, and as an injustice has, doubtless unwittingly, been done Governor Richard Yates of Illinois, an executive whom the Illinois State Medical Society took occasion to highly compliment in formal resolutions adopted less than a month ago, I beg leave to state the facts in the case.

The editorial states that the bill was vetoed "simply on the ground that the examining board was to be appointed from names selected by the Illinois State Medical Society." Again, "the governor objects to this as taking from the executive his prerogative, and, we might add, his political perquisites."

The above must be a mistake, as the Illinois State Medical Society is not mentioned in the bill (Senate Bill No. 147).

The bill provided for the appointment of an examining committee by the State Board of Health, from names submitted by the Illinois State Association of Graduate Nurses; the appointment of one board by another. The board of health, not the governor, was clothed with the appointing power. Furthermore, appointment from these nominations was mandatory as the word "may" in the law means "shall." This practically gave the appointing power to the Nurses' Association, and at the same time held the governor responsible for the work of the board over which he had no control.

The governor says in his veto:

> I veto this bill because I do not believe there was due deliberation in its consideration and passage, and because it is not consistent with the general policy of the constitution.
>
> The theory of the constitution is, that the governor of the state, by and with the advice and consent of the state senate, shall nominate and appoint the state officers, and that the state officers shall perform state duties. . . . The performance of said duties by persons who are not state officers is not contemplated by the constitution, and was not contemplated by the framers thereof. . . . When the people shall deem it wise to commit the performance of the official duties of the state to persons who are not state officers, they may revise the policy of the present constitution by amending the same. . . . Until then, state duties should be performed by state officers and not by persons selected or nominated by societies. . . . The tendency to create boards consisting of persons whose selection is absolutely dictated by mere volunteer associations of persons who gather themselves together and constitute a society, is a tendency that should be checked.

The above is in accord with the decision of the Illinois Supreme Court in 1899 in the case of Charles W. Lesher vs. the People of the State of Illinois.

In the matter of appointments by the executive, the governor thus takes the ground that the constitution guarantees to the governor the right not only to appoint, but also to nominate and appoint. This being the case, it is his opinion that any statute which undertakes to nullify and abridge the constitution must be considered not only a violation of the constitution, the fundamental law of the state, but also wholly wrong in policy and principle.

That Governor Yates does not object to "the assistance of a qualified organization in the selection of persons for a purely professional function" the Illinois State Medical Society is in a position to testify. At the beginning of his administration the governor submitted to the judicial council of the society the names of many persons seeking medical appointments under the state government, and asked for recommendations. The judicial council by resolution has since expressed its appreciation of this act of Governor Yates. In the presidential address in 1901, the president of the state society stated that Governor Yates had kept his ante-election promises, and had given the society all possible consideration. As late as two months ago the legislative committee of the Illinois State Medical Society, in a circular letter sent to over 5,000 physicians, stated that Governor Yates had given the medical profession of Illinois more consideration than any governor of recent years and that he was in hearty sympathy with the high ideals entertained by the profession.

In conclusion permit me to quote from the remarks of Governor Yates in his veto of the Dental Examiners' Bill on May 15, 1903:

> The present executive is willing, and doubtless any other executive will be willing to listen to proper and reasonable recommendations, and it may be in the appointment of professional boards every executive will, in nine cases out of ten, select as members the persons recommended by the profession affected, inasmuch as the executive will doubtless assume that the profession affected is more interested and better informed than any other persons or citizens can possibly be.

GEO. W. WEBSTER,
President State Board of Health.

Maternal Impressions.

TELL CITY, IND.

To the Editor:—In THE JOURNAL of April 4, Dr. E. T. Shelly relegates the maternal-impression theory to the medical lumber-room, a very comfortable, if not a very satisfactory, way of disposing of all abstruse theories which are not clearly understood. The difficulty, however, we meet at the very threshold of such a happy disposal of the subject, makes it a herculean task, for are there not on every hand too many and too conspicuous cases to satisfactorily dispose of them with a wave of our wand? When Dr. Shelly declares there is no anatomic or physiologic connection between the mother and child he assumes a conclusion not thoroughly established, and which may be a figment of the fancy. If, however, there is no such connection, it does not follow that there is an absence of psychologic connection. Surely we witness the too often painful effect of environment during the gestatory period. The mother may not be wholly blamable if her offspring, gestated in an atmosphere reeking with all that is base and degrading, is born a pitiable object. True, the child born in a den of vice and infamy may, by inherent qualities or central impetus, burst the restraints of infamy and burn a star of light over a sea of corruption. Too often, alas, the reverse is true.

There is a subtle and possibly a reciprocal connection between the mother and the fetus during the entire embryonic life. Nor is she blamable if, during gestation, she be so rudely shaken from the poise of harmony by some sudden shock that the brunt is borne by the offspring ever after. I have witnessed too many well authenticated cases to doubt it for a moment. The mother should have the most harmonious, beautiful and elevating surroundings during gestation. The restraints of toil and care should irk her not. She should not be stewed with worry or spitted with starvation. She should be placed on a well-guarded pedestal, canopied with comfort and gently basted with sweet-scented bouquets. Her make-up is intricate. She is a problem, to be solved by no simple rule of mathematics. On her environment hangs the future welfare of posterity. Her mental impressions may wonderfully impress the embryo, may mark it, ay, may destroy its harmony, its usefulness, its life.

F. ANSON EVANS.

Preserved in Wax.

MUSKEGON, MICH., May 22, 1903.

To the Editor:—The following case illustrates the remarkable preservative properties of cerumen: J. W. S., age 63; white; Civil War veteran. A beetle of the species *Tenebrio molitor* entered right ear one evening in August, 1861, while patient was in Camp Good Hope, near Navy Yards, Washington, D. C. Patient immediately applied to regimental surgeon, who, failing in efforts to remove insect, applied olive oil to ear and instructed patient to return to tent and lie on right side, and suggested that the bug would probably be found on blanket in the morning. Pain in ear kept patient awake until nearly morning and when awakened ear felt much better, and patient forgot to look on blanket for insect, which he supposed had escaped from the ear. Since insect entered ear, patient has been able to hear but faintly with right ear.

Patient applied to me for relief from deafness May 8, 1903. On examination, I found external canal filled with cerumen. Applied solvent and instructed patient to return in twenty-four hours. After syringing the ear the following day, I found the beetle, which was ⅝ inch in length and slightly greater in width than the normal caliber of the canal and with ear tenaculum, removed it, not without some difficulty. The head of insect lay within one line of tympanum.

After 41 years and 8 months the beetle was in perfect state of preservation; legs, feelers and all appendages intact. One week after removal the external canal appeared normal and the hearing is nearly normal. F. B. Marshall, M.D.

Plaster-of-Paris Bandages.

Toledo, Ohio, May 8, 1903.

To the Editor:—It is not generally known that the late Dr. Hezekiah P. Mead of Morrisville, Madison County, N. Y., who died last year, was the first to discover the practicability of applying the plaster-of-paris bandage to the treatment of fractures and other displacements in which it is so universally used by the profession throughout the land. This was early in the year 1860.

With an utter lack of any thirst for notoriety, and content with his mere contribution to the profession and to the good of humanity, he gracefully allowed the name of another skilled and more prominent surgeon of the time to be credited with this valuable discovery.

Through intimate association and personal knowledge of the facts at the period named, I have felt it incumbent on me to call attention to the above fact, in justice to a man of consummate skill and the highest citizenship. In a personal reminiscence which I caused to be published in the *Toledo Blade* in 1901, I gave in some detail the circumstances which first led to the adoption of this new use of a common and well-known article, and which I believe I am able to substantiate if desired.

N. B. Bacon.

Failure of the Eddyites in Arkansas.

Winfield, Ark., May 12, 1903.

To the Editor:—I see in The Journal, May 9, that the Eddyites failed to receive a charter in Philadelphia. At the past session of the Arkansas legislature these people got a bill through the senate to exempt them from Section 13 of the recent medical act of the state, but in the house we managed to put an amendment on the bill "providing that they receive no pay for their practice." The senate never concurred in the amendment, so they are out here. Cheves Bevill.

Triplets.

Hope, Ark., May 19, 1903.

To the Editor:—May 14 I delivered Mrs. M. of triplets, two girls, one boy. The weights of the two girls were 5½ and 6 pounds and of the boy 6½ pounds. They are all hale and hearty and at this time are doing nicely. Mrs. M., who is the mother of four other children, is also doing nicely. She had the easiest time of any of her confinements.

J. H. Weaver.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

DO NEGROES RECOVER FROM PHTHISIS?

Albuquerque, N. M., May 13, 1903.

To the Editor:—I desire to learn through the columns of The Journal, from one or more physicians residing in southern states and who have had any considerable number of cases of pulmonary tuberculosis among the African race, if they know a recovery among negroes suffering from this disease. I desire the information for statistical use and will consider it a great kindness from anyone who can give me such aid, either by personal communication or through The Journal. Francis Crosson.

SALOL COATED IPECAC PILLS.

Newman Grove, Neb., May 15, 1903.

To the Editor:—Will you please inform me where I can get ipecac pills that are coated with salol? D. B. McMahon, M.D.

Ans.—We are unable to learn of any such ready-made pills. Any of the large pharmaceutical houses, however, will prepare these for you, or perhaps a druggist in your own city will be able to do the same satisfactorily.

PINK REACTION IN URINE.

Philadelphia, May 18, 1903.

To the Editor:—With reference to the pink coloration of urine noted by Dr. Minter in The Journal, May 16, p. 1386, on addition of nitric acid: I have observed such a reaction in a case in which also tubercle bacilli were found in the urine, and the same observation has been made, I believe, by Dr. Joseph Walsh of this city.

Augustus A. Eshner.

PHOSPHORUS ELIMINATION IN TABES.

Matagorda, Texas, May 6, 1903.

To the Editor:—Has it been observed that there is an increased elimination of phosphorus through the urine in tabes dorsalis? And, if so, has the administration of phosphoric acid been recommended for treatment of this disease? S. A. F.

Book Notices.

The Prevention of Disease. Translated from the German with an Introduction by H. Timbrell Bulstrode, M.A., M.D., D.P.H. In Two Volumes. Cloth. Pp. 1063. Net Price, $3.75 per Volume. New York: Funk & Wagnalls Company. 1903.

This is a translation of a well-known German work, a composite production by numerous teachers. The names of the authors give, in themselves, a fairly good idea of the merits of the work, including as they do some of the most eminent specialists and internists of the German Empire. There are, of course, in a work like this some divergences of opinion and in one particular it seems peculiar that a book coming from the publishing house of Funk & Wagnalls should contain arguments advising the moderate use of alcohol and even occasionally the taking of a little more than usual on festive occasions, as suggested in Dr. Einhorn's article on the "Prevention of Diseases of the Digestive Organs." In another article, that of Fuchs on the "Prevention of Mental Disease," total abstinence seems to be advocated, at least on the part of the physician. The two volumes as a whole, however, are a valuable addition to the hygienic medical literature in our language.

Therapeutics of Infancy and Childhood. By A. Jacobi, M.D., LL.D. Third Edition. Cloth. Pp. 559. Price, $3.50. Philadelphia and London: J. B. Lippincott Co. 1903.

As the author says in his introduction, while many additions have been made to the book, there have been no actual changes in its general contour. It is the revision of a well-known work which has already received its share of favor with the profession. The author's views in regard to the at present much discussed question of infant feeding are stated by him in the beginning, that there will be no unanimity on the question as long as infants insist on being individuals, having their own special constitutional idiosyncrasies. The author acknowledges his indebtedness to the contributors to the Festschrift published in his honor between two and three years ago, than which he says he knows of no collection of an equal number of monographs on scientific and practical subjects of equal value connected with pediatrics.

Book on the Physician Himself and Things that Concern His Reputation and Success, by D. W. Cathell, M.D. The Twentieth Century Edition, Being the Eleventh Edition Revised and Enlarged by the Author and His Son, William T. Cathell, A.M., M.D. Cloth. Pp. 411. Price, $2.50 net. Philadelphia: F. A. Davis Company. 1902.

The appearance of the eleventh edition of a work ought to be sufficient evidence of its popularity. This book has been before the medical public for many years. There is no other exactly like it in its combination of worldly wisdom and ethical advice. Numerous quotations interpolated in the book remind one of the Latin quotations in old Burton's "Anatomy of Melancholia," but they are so funnily chopped up and sawed off in some cases that the impression is somewhat different. We do not consider them a valuable addition.

Physical Chemistry for Physicians and Biologists. By Dr. Ernest Cohen, *Professor of General and Inorganic Chemistry in the University of Urecht.* Authorized Translation from the German. By Martin H. Fischer, M.D., Instructor in Physiology in the University of California. Cloth. Pp. 343. New York: Henry Holt & Co. 1903.

Nowadays when the ions, electrolytes, etc., are beginning to play such an important part in the discussions of therapeutics and physiology, a work like this translation of Prof. Cohen's should be welcomed. As a preliminary note to the American translation Prof. Jacques Loeb says it not only serves as an introduction to physical chemistry, but also teaches the physician and biologist how to apply this science to medical and biologic problems. We admit that in some respects the book will itself require some introductory study by a large majority of practitioners, but this is not an avoidable defect. The translator has evidently done his work well and has made his matter as clear as possible considering the nature of the text.

Marriages.

Rachel Robbins, M.D., to William E. Stieren, M.D., both of Pittsburg, Pa., April 30.

John H. Jenness, M.D., Rising Sun, Md., to Miss M. Bessie Marshall, at Baltimore, May 6.

Mark Monroe Evans, M.D., Le Grand, Iowa, to Miss Mary Carolyn Dodd of Montour, Iowa, April 29.

E. A. Cantonwine, M.D., Van Cleve, Iowa, to Miss Daisy M. White of Rolfe, Iowa, at Marshalltown, Iowa, May 6.

Deaths.

Thomas G. Morton, M.D., who for years has been one of the most prominent surgeons of Philadelphia, died at Cape May of cholera morbus May 20. He was born Aug. 8, 1835, in Philadelphia, his father being Dr. S. G. Morton, a distinguished physician and scientist. Graduating from the Medical College of the University of Pennsylvania in 1856, Dr. Morton served as resident physician in the Pennsylvania Hospital, where he later succeeded Dr. Joseph Pancoast as attending surgeon. He was one of the founders of the Polyclinic and Orthopedic hospitals. During the Civil War he organized a military hospital, and became surgeon to other army hospitals. His many services to the state included chairmanship of the committee of the commission for the erection of the State Hospital for the Insane for the southern district of Pennsylvania. He has served as vice-president of the Society to Protect Children from Cruelty. He was at one time a commissioner of the State Public Charities and again chairman of the State Committee on Lunacy. The clinical lectures he held at the Pennsylvania Hospital have been attended by thousands of students. Dr. Morton was a member of various foreign and American professional societies, was a frequent contributor to current medical literature, and has written standard works on medical subjects, including "The Transfusion of Blood and Its Practical Application." Since 1890 he has been an active member of the Board of Public Education. Deceased is survived by his wife, three daughters and two sons, one of the latter being Dr. Thomas S. K. Morton.

Adelbert H. Tagert, M.D. University of Vermont, 1866, died at his home in Chicago, May 27, of pneumonia, after an illness of a few days, aged 57. Dr. Tagert, after practicing in Buffalo for two years, came to Chicago thirty years ago, where he has since resided. He was surgeon of the C. M. and St. P. Railway for seventeen years, and at the time of his death was president of the Kedzie Hospital. He was a member of the Chicago and Illinois State Medical societies and of the American Medical Association.

Florence W. Hunt, M.D. Northwestern University Woman's Medical School, 1894, formerly a member of the Illinois State Board of Health, neurologist to St. Joseph's Hospital, and a member of the Chicago and Illinois State Medical societies and the American Medical Association, died in Milwaukee May 27. This news is received as we go to press, and a further notice will be given next week.

H. Grey Latham, M.D. University of Virginia, Charlottesville, 1851, died from heart disease of long standing at his home in Lynchburg, Va., May 5, aged 72. He was commander of the famous Latham battery during the Civil War, and was for several terms president of the Virginia Medical Board.

William R. Hayden, M.D. Eclectic College of the City of New York, 1867, died at his home in Bedford Springs, Mass., April 29, aged 83. He was president of the New York Pharmaceutical Company for 45 years.

Charles Clayton Abernathy, M.D. University of Pennsylvania, Philadelphia, 1851, of Pulaski, Tenn., who achieved distinction as a surgeon in the Confederate service, was found dead in bed, April 27, aged 75.

Edward De La Granja, M.D. Central University, Madrid, Spain, 1855, a member of the Royal Society of Medicine; brigade surgeon in the Crimean War, and for many years a resident of Boston, died at his home in that city, May 10, aged 73.

George W. Hunton, M.D. Jefferson Medical College, Philadelphia, 1847, died at his home in Virginia, from asthma, aged 77. During the Civil War he was surgeon of the Eighth Virginia Infantry, C.S.A.

Alfred E. Moore, M.D. Medical Department Iowa State University, Iowa City, 1887, died at his home in Wayland, Iowa, from pneumonia, April 21, after an illness of two weeks, aged 40.

Augustus S. Long, M.D. Long Island College Hospital, Brooklyn, 1865, died at his home in St. Joseph, Mo., from inflammatory rheumatism, April 30, after an illness of two weeks, aged 62.

John C. Brown, M.D. Atlanta Medical College, 1875, of Whitesburg, Ga., died at the home of his daughter in Carrollton, Ga., April 27, from paralysis, after an illness of three weeks.

Walter Bacon Morrison, M.D. Long Island College Hospital, Brooklyn, assistant surgeon in the Civil War, died at his home in Muskegon, Mich., May 2, after a lingering illness, aged 65.

James Aloysius Roache, M.D. Long Island College Hospital, Brooklyn, 1891, died at his home in Brooklyn, from cirrhosis of the liver, May 3, after an illness of four weeks, aged 44.

Alfred B. McChesney, M.D. University of Michigan, Ann Arbor, 1853, a surgeon in the Army during the Civil War, died at his home in Chicago, from pneumonia, May 7, aged 75.

Fieldon R. Waggoner, M.D. Missouri Medical College, St. Louis, 1878, died at his residence in Sacramento, Cal., April 28, from paralysis, after an illness of four days, aged 67.

Samuel P. Buck, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1853, died at his home in West Woolwich, Maine, April 22, after a brief illness, aged 77.

Harold Hamilton Haas, M.D., passed assistant surgeon, U. S. Navy, died from the effects of a self-inflicted gunshot wound of the head, at Staunton, Va., aged 30.

Jesse J. Morgan, M.D. College of Physicians and Surgeons, Baltimore, 1883, died at his home in Dacusville, S. C., April 27, after an illness of one year, aged 42.

James W. Taylor, M.D. Jefferson Medical College, Philadelphia, 1854, died suddenly at his home in Leesburg, Va., from heart disease, April 28, aged 70.

James M. Clopton, M.D. New York University, 1867, died suddenly from heart disease at his home in Mercury, near Huntsville, Ala., April 24.

John H. Salyer, M.D. Tulane University, New Orleans, 1899, of Ledbetter, Texas, died at Navasota, Texas, after a long illness, April 28, aged 29.

Bernardus Schutte, M.D. University of Leyden, Holland, 1875, died at his home in Grand Rapids, Mich., April 30, from aortic aneurism, aged 56.

Griffin Reno, M.D. Albany Medical College, 1862, of Bradford, Pa., died at Venus, Venango County, Pa., April 30, from heart disease, aged 60.

Sylvanus L. Roberds, M.D. Kansas City Medical College, 1876, of Myrtle Point, Ore., died recently at a hospital in Portland, Ore., aged 56.

Lisle C. Waters, M.D. Rush Medical College, Chicago, 1880, died at his home in Chicago, April 30, from anemia of the aorta, aged 54.

William Deegan, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1884, died at his home in Chicago, May 6.

James C. Rhodes, M.D. Geneva (N. Y.) Medical College, 1847, died May 1, at his home in Stillwater, Minn., aged 79.

Joseph B. Le Matty, M.D. Missouri Medical College, St. Louis, 1877, died at Bardolph, April 5, aged 56.

Henry Eversman, M.D. Medical College of Ohio, Cincinnati, 1861, died at Effingham, Ill., April 7, aged 66.

Elizabeth McKitterick, M.D. Woman's Medical College, Chicago, 1880, died recently at Guthrie, Okla.

Thomas H. Mangum, M.D., retired, of Trenton, Texas, died at his home in that place, April 29, aged 69.

William A. Noel, M.D. University of Louisville, 1843, of Pine Bluff, Ark., died recently.

R. B. Cotton, M.D. Toronto University, 1886, died in Regina, N. W. T., May 6, aged 48.

Deaths Abroad.

H. Gutschow, M.D., chief of the medical department of the German navy, died at Berlin, April 23.——**Felix Beetz, M.D.**, a former collaborator on the *Deutsche Med. Wochft.* and the *Reichs-Medizinal-Kalender*, died at Berlin, April 11, aged 54. ——**G. Nepveu, M.D.**, professor of pathologic anatomy at Marseilles, author of numerous works on surgery and bacteriology. ——**J. La Bonnardiere, M.D.**, professor of therapeutics at the French medical college of Beyrouth.——**M. Rio de la Loza, M.D.**, president of the section of medical physics and chemistry of the Mexican Academy of Medicine, died at Mexico, April 9.

Dr. F. Colzi, professor of surgery at Florence, one of the leading surgeons of Italy, died at Florence, April 10, aged 47, from the results of an accidental gunshot wound which shattered his forearm. Tetanus developed and proved rapidly fatal, notwithstanding amputation of the arm.

Dr. Anton Bumm, of Munich, professor of psychiatry, died at his home, April 13, from gallstone disease, aged 54.

Dr. E. Oehl, professor of physiology at Pavia, died April 5, aged 76.

Dr. G. von Veit, professor of gynecology at Bonn, 1863 to 1893, died at Gevelsdorf, April 20, aged 79.

State Boards of Registration.

The next Illinois examination will be in the Seventh Regiment Armory, Chicago, June 1 to 3. This is a special examination for physicians only. The next regular examination will be at the same place, July 22.

Texas.—The next meeting for the examination of applicants who desire to practice surgery, medicine and midwifery in Texas will be held in Austin, June 15. For blanks, rules and any other information, address Dr. M. M. Smith, the secretary, Austin, Texas.

New Hampshire.—The next examination will be held in Concord, June 23-24. By an amendment to the medical registration law, enacted by the legislature at the session of 1903, *hotel* physicians, employed by the landlord of a summer hotel in the care of his guests or employes, will hereafter be obliged to secure a license to practice, in accordance with Chapter 63 of the Session Laws of 1897. This license can be obtained only by examination.

Reciprocity.—There was held in Chicago, April 23, a meeting of the representatives of the medical examining boards of Indiana, Ohio, Iowa, Kansas, Michigan and Wisconsin. An organization was formed entitled the American Confederation of Reciprocating, Examining and Licensing Medical Boards of the United States of America, having for its object the establishing of reciprocal relations between the medical examining and licensing boards of the United States. The basis for reciprocal medical registration is stated as follows:

> For the purpose of establishing medical reciprocity among the states composing it, the American Confederation of Reciprocating Examining and Licensing Medical Boards does hereby agree to the following propositions as a basis of reciprocal medical registration:
>
> (*a*) That a prerequisite to reciprocal registration, the applicant therefor shall file in the office of the board of the state of which he is a licentiate such evidence as will enable the said board to certify that he is of good moral and professional character. Such certificate shall be filed with his application for reciprocal registration in *another state*.
>
> QUALIFICATION 1.
>
> (*b*) That a certificate of registration showing that an examination has been made by the proper board of any state, on which an average grade of not less than 75 per cent. was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the state where reciprocal registration is sought, may be accepted, in lieu of examination, as evidence of qualification. Provided, that in case the scope of the said examination was less than that prescribed by the state in which registration is sought, the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.
>
> QUALIFICATION 2.
>
> (*c*) That a certificate of registration, or license issued by the proper board of any state, may be accepted as evidence of qualification for reciprocal registration in any other state. Provided, that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date thereof was prior to the legal requirement of the examination test in such state.

Texas Report.—Dr. M. M. Smith, Austin, secretary of the Board of Medical Examiners for the State of Texas, reports the examination held at Austin, April 20 to 23, 1903, as follows: Subjects, 13; questions, 135; percentage required, 75; written examination; examined, 97; passed, 87; failed, 10, including one applicant for license as a midwife.

* Undergraduates.

Examination Board in Kentucky.—At the annual meeting of the Kentucky State Board of Health it was recommended that the board refuse recognition to the graduates of colleges where it could be proven that the college had cut fees from the advertised rates, or had violated other entrance requirements. A suggestion was made that the board amend its requirements so as to make it an examining board for the examinations of applicants to practice in the state, or that the legislature be petitioned to create an examining board, to be composed of men in no way connected with medical colleges. To meet this emergency it was stated that from this date no member of the present board will have any connection with a medical college.

Idaho Report.—Dr. R. L. Nourse, Hailey, secretary of the Idaho State Board of Medical Examiners, reports the examination held at Boise, April 7, 1903, as follows: Number of subjects examined in, 12; total questions, 120; percentage required to pass, 75; written examination; total number examined, 22; number passed, 13; failed, 9.

Association News.

New Orleans Arrangement Committee Finds a Balance.

The Committee on Arrangements met at New Orleans, May 14, and found that after paying all bills there would be a balance on hand of $1,700. This saving resulted from there being less expense than had been planned for some receptions, and from an increase in the receipts from the exhibits over that which had been counted on. Of this balance, $750 was unanimously voted to the Confederate Reunion Committee, with which to entertain the veteran surgeons of the Army and Navy at their convention. In view of the courtesies extended by the Young Men's Christian Association, the Touro Synagogue and the Carondelet M. E. Church, and in appreciation of the use of their meeting halls, $25 was voted to each. The remainder of the surplus it was voted to contribute to the fund being raised for the establishment of a branch of the Pasteur Institute in New Orleans. The Committee passed a vote of thanks to the newspapers, telephone and telegraph companies, the clubs who extended courtesies, prominent citizens who assisted in various ways and to numerous other persons and bodies who assisted in making the New Orleans Session such a brilliant and successful convention. The Arrangement Committee then adjourned sine die.

Medical Organization.

Manhattan (Kan.) Medical Society.

Nine physicians of Manhattan met, April 20, and organized a medical society with the following temporary officers: Chairman, Dr. Charles F. Little; secretary, Dr. James D. Colt, Jr.

Carroll County (Ga.) Medical Society.

The physicians of Carroll County met at Carrollton for organization and elected Dr. Buna C. Powell, Villa Rica, president; Dr. W. Lee Fitts, Carrollton, vice-president; and Dr. J. F. Cole, Carrollton, secretary and treasurer.

Cedar County (Iowa) Medical Society.

This society perfected its organization at Tipton, April 29, by adopting a constitution and by-laws and electing the following officers: Dr. L. W. Baker, Stanwood, president; Dr. H. R. Chapman, Bennett, vice-president; Dr. Roscoe A. Nash, Tipton, secretary, and Dr. Louis J. Leech, West Branch, treasurer.

Lyon County (Kan.) Medical Society.

At the annual meeting held in Emporia, May 5, the society voted to affiliate with the district and state societies along the lines suggested by the American Medical Association. Dr. John M. Parrington was elected president; Dr. Frank A. Eckdall, vice-president, and Dr. John M. Poindexter, secretary and treasurer, all of Emporia.

Crawford County (Ohio) Medical Society.

Representative medical men of Galion, New Washington, Crestline and Bucyrus, met at the latter city, May 1, and after an address by Dr. Theodore W. Rankin, Columbus, councilor for the sixth district, perfected organization by adopting a constitution and by-laws in conformity with that suggested by the American Medical Association, and electing the following officers: Dr. Burton R. Miller, New Washington, president; Dr. Thomas L. Brown, Galion, vice-president; Dr. Robert S. Reid, Bucyrus, secretary; Dr. Charles E. Trimble, Crestline, treasurer, and Dr. Arthur M. Duncan, Bucyrus, delegate to the state society.

Societies.

COMING MEETINGS.

Indian Territory Medical Association, South McAlester, June 2-3.
Medical Society of the State of North Carolina, Hot Springs, June 2.
Ohio State Medical Society, Dayton, June 3-5.
Rhode Island Medical Society, Providence, June 4.
Wisconsin State Medical Society, Milwaukee, June 3-5.
Maine Medical Association, Portland, June 3-5.
Indiana State Medical Society, Richmond, June 4-5.
Medical Society of Delaware, Dover, June 9.
Massachusetts Medical Society, Boston, June 9-10.
Michigan State Medical Society, Detroit, June 11-12.
Minnesota State Medical Society, St. Paul, June 17.
Medical Association of Montana, Helena, June 17-18.
Medical Society of New Jersey, Asbury Park, June 23-25.

The University of Toronto alumni, resident in California, held their first meeting March 27. The organization starts out with a membership of 22. There are nearly 60 graduates and undergraduates in California.

Medical Association of the District of Columbia.—The annual meeting was held in Washington, April 7, at which the following officers were elected: President, Dr. Albert F. A. King; vice-presidents, Drs. Raymond T. Holden, and Louis Mackall, Jr.; secretary, Dr. Daniel W. Prentiss, and treasurer, Dr. Frank Leech, all of Washington.

Litchfield County (Conn.) Medical Association.—This association, the oldest of its kind in the United States, held its one hundred and thirty-ninth annual meeting at Winsted, April 29. Dr. Jerome S. Bissell, Torrington, president; Dr. George H. Knight, Lakeville, vice-president; Dr. Albert E. Cobbs, Falls Village, secretary and treasurer, and Dr. William S. Hulbert, Winsted, reporter.

Sanitary Officers of Baltimore County.—At the meeting at Towson, May 6, the following officers were elected: Dr. James F. H. Gorsuch, Fork, president; and Dr. T. Ross Payne, Corbett, secretary. A resolution was adopted exonerating Dr. John C. Schofield, Baltimore, from any blame for the escape of smallpox suspects from the Homburgville camp, which had been criticised so severely by the health commissioner of Baltimore.

Western Alumni Association of the University and Bellevue Hospital Medical College.—The third annual meeting and banquet was held in Chicago, April 30. Dr. George N. Kreider, Springfield, Ill., was the toastmaster. The following officers were elected: President, Dr. David W. Graham, Chicago; vice-presidents, Drs. Charles C. Hunt, Dixon, Ill., Joseph M. Patton, Chicago, and James A. Duncan, Toledo, Ohio; secretary, Dr. Willis O. Nance, Chicago, and treasurer, Dr. Calvin M. Fitch, Chicago.

Johns Hopkins Medical School has required the bachelor's degree for admission, and that such is now the requirement of the medical school of Harvard and that of Baltimore University. The medical school of Western Reserve University requires the equivalent of three college years; the medical school of the universities of Michigan and Chicago two, and of the University of Minnesota one. Other leading institutions emphasize the need of a general education as preliminary to medical study by encouraging the taking of a bachelor's degree before asking of them matriculation in medicine. The presidents of Yale, Columbia, Harvard and Cornell have given lengthy consideration to this matter in late reports, President Eliot advocating the bachelor's degree before professional study, and President Butler declaring it is the settled policy at Columbia that its technical and professional schools shall rest on a college course, though not necessarily four years of liberal study.

A National College Association.

No platform was adopted by this conference, nor was any policy formulated, but the conference ordained its own perpetuation in the appointment of a committee, President James, chairman, to select a commission of fifteen, which should report a program and plan of organization and membership one year hence, by this act providing for a new factor in the control of higher education in this country—a national college association.

The Speakers on the Medical Standpoint.

The subjects discussed by the conference were:

> Has the college a field peculiar to itself, not covered by the technical school or by the demands of preparation for the professional school?
>
> Is it desirable that the college course should be reduced in time from four to three or even two years and correspondingly in amount of work?
>
> What subjects in the typical college course can be accepted by the professional school as qualifying in part for the professional degree so as to shorten the time required for graduation in the professional school?
>
> If reduction is allowed, should it be (*a*) by acceptance of credits in the college of liberal arts for work done in the professional school, or (*b*) by acceptance in professional school for work done in the college of liberal arts, or (*c*) by combining these plans?
>
> The relation of the technical school to the college.

On the third topic the speakers of professional training and connections, who sought to show how the independent college and the professional school, independent or with university relations, might work together and so shorten the period of their several courses, were Dr. Arthur R. Edwards, of the Northwestern University Medical School; Dr. R. McE. Schauffler, secretary of the faculty of the Kansas City Medical College; Dr. Frances Dickinson, dean of Harvey Medical College, and Prof. W. A. Locey, of the chair of zoology in Northwestern University. Dr. Edwards held that if medicine grows in the next ten years as it has in the last a medical course will require five or six years of study, and the courses of the college and medical school must overlap. He would have the college teach some of the sciences that are preparatory to medicine, for instance, chemistry and the principles of anatomy and histology, and so would demand of the college course that it do 60 to 80 per cent. of the work done in the first year of the medical school. In such way he would base a degree on a six years' pursuit of continued courses. On the other hand, from the point of view of the college, Professor Locey held that such work as the professional school offered for allowances in the college of liberal arts should be work done in a broad and liberal, and not an ultra-professional spirit. So taught, chemistry, physiology, histology, embryology, neurology, bacteriology and pathology, all sciences contributing to a knowledge of organic nature, might be accepted by the college.

Dr. Dickinson contended that high school graduates are not fitted for medicine, and that some college training is essential to medical study. In most medical schools, she said, the first two years belong to the college courses. Dr. Dickinson plead for one year's advance standing for five or more years of business training.

The Need of a College Course Foundation.

Dr. Schauffler said that, as a graduate of the medical department of Columbia, he wanted to say that although President Butler says that to require an A.B. for admission is economically impossible, and from the standpoint of social service unwise, nevertheless, one quiz master in that institution was not afraid to make a bachelor's degree an absolute condition for entrance to his quiz. With fifteen men from small colleges and from the academic departments of Yale and Princeton, taught largely in his office by methods of college rather than university, he took all three of the prizes at Columbia and in competition with all medical colleges in New York and many other centers east took twelve of the thirty best hospital appointments in the city. This was not for one year, but was about his average. Dr. Schauffler further said that he never knew of a man from the short-cut Columbia combined course who ever took a Harzen prize or secured a conspicuously good hospital appointment. It often happened that some other student, even one direct from a secondary school, by fine memory and application, stood higher on theoretical work than the Eliot quiz man, but when it came to practical examination in the diagnosis of unknown cases the ability to reason quickly and correctly, the poise, as some one here to-day has said, the "flexibility" of the college graduate always carried him through the ordeal successfully. What is the present situation? We are giving one year's credit on the medical course for an A.B. degree. The theory of this credit is involved in the question, "What subjects in the college course may be accepted for credit in the medical course?" We should say physics, biology, including histology and embryology, chemistry, physiology, comparative anatomy and botany, with a trend toward pharmacy, However, many of these subjects are the ones which, from lack of equipment or sufficiently large faculties, are most poorly taught in the colleges surrounding us. The year's credit for the A.B. is then often unsatisfactory, but we can struggle along with it. He said further:

> Now comes the proposition from the universities to give the combined course in six years. It is flatly impossible for us to give two years' credit for the bachelor's degree. You may say that if the independent school can not stand the competition it must, in the course of evolution, go to the wall. That day must be sometime distant, however, in our part of the country, where the neighboring state universities are in small towns and can not, for lack of clinical facilities, entirely replace the city school. We are not whining over the pressure which comes from the universities on account of wealth and enlarged facilities. While it is requiring much effort and sacrifice, we must hold our own or we are not worthy to survive. What we do object to is the university throwing in an A.B. degree "to boot" for only two years, as an inducement to the student to spend his entire time within its walls. Until it is accepted by a reasonable majority of institutions that two years is sufficient time for a college course, we hold that this action is an effort to take an unfair advantage.
>
> Of course we can immediately seek alliances with independent colleges surrounding us for joint traffic arrangements. As local conditions are at present in the West this will lead to much confusion and, moreover, give an opportunity for the college which is not over-scrupulous in its scramble for students to let down the bars just at a time when there seems hope of enforcing uniformity and thoroughness in medical education.
>
> In my opinion our *goal, which we can not* in the West reach at a single bound, is:
>
> 1. Two years of a college course as a requirement for admission to a medical school.
> 2. No advanced *standing for a degree per se,* but only for specific groups of scientific subjects which adequately cover part of the first and second years of the medical course.

AMERICAN UROLOGICAL ASSOCIATION.

Second Annual Meeting, New Orleans, May 8 and 9, 1903.

The President, Dr. Ramon Guiteras, New York, in the Chair.

The Present Status of Urology in the United States.

Dr. Guiteras, in his president's address, reviewed urology as a specialty, distinct from surgery in general. He showed what this Association, modeled on the plan of the Societe d'Urologie Francaise, even in its brief existence, had done to establish the separate existence of urology. He further showed the need of such an organization which but a year ago had its first annual meeting. It then counted but forty members, while now it has over 150 of the most eminent men in our land.

Drs. Lydston, Guiteras and Valentine showed instruments.

The Diagnosis of Tuberculosis of the Kidney and Ureter.

Dr. J. Wesley Bovée, Washington, emphasized the need of establishing a positive or negative diagnosis, not only by cystoscopy but also by cultures and animal inoculations, by determining the presence or absence of the tubercle bacilli.

Prostatectomy.

Dr. John B. Murphy, Chicago, gives preference to the radical operation over any of the palliative measures advocated.

Dr. Willy Meyer, New York, recited the results in fifty-nine prostatics on whom he had operated by the Bottini incisor in the past five years. His experience in these cases led him to advocate the use of the Bottini instrument.

Dr. Granville MacGowan, Los Angeles, reported a patient whose prostate he had enucleated for sarcoma. As the patient had had no recurrence in four years and finally died from other causes, the author believed that early radical operation in such cases should be performed.

DISCUSSION.

Dr. McRae believed that the suprapubic operation for prostatectomy was the easier operation for the surgeon with a good sense of touch and not afraid of the bugbear of hemorrhage. He believed continuous catheterization was an important measure.

Dr. Ferguson, Chicago, believed the perineal route was the operation of choice and the route to take in the large majority of cases. He described his method of procedure and preferred removing the prostate piecemeal. The tendency to do a complete prostatectomy, he thought, was passing, and more attention being given to the removal of the obstruction only.

Dr. Lydston, Chicago, condemned any *tendency to routinism* and did not believe that any considerable number of cases could be operated on by any one method. There was a time when he thought the suprapubic method was the proper one. He now believes that the combined method is the ideal way, though, unfortunately, we usually have a septic bladder to deal with. The cases are usually brought because nothing else can be done for them, and they have infected bladders and surgical kidneys. For this reason he emphasized the need for earlier operations in most cases, and thought the results would then be as favorable as in operations on other portions of the tract.

Dr. MacGowan said that wherever we have reason to suspect cancer of the prostate we should use the Bottini operation. There is practically no danger from hemorrhage. Wherever the patient is too weak to be confined to bed for any considerable time, use the Bottini method. Wherever the collection of urea is below 20 g. per day, use the Bottini method.

Dr. Guiteras spoke from the standpoint of prostatic obstruction, the object of the operation being to enable the patient to empty his bladder, or as nearly as possible the actual size of the prostate remaining a secondary question. Formerly he had been enthusiastic in advocating the suprapubic operation, but has now almost abandoned it and would perform this operation only in cases where the prostate was high up on the bladder. In attacking through the perineum he employs a large perineal tube and leaves this in position for a week or ten days. This gives the space where the prostate has been a chance to close up. As an aid to the finger he advocated the use of the prostatic depressor which enables the operator to push the prostate down into reach. There are two varieties of prostatic enlargement—the variety which can be shelled out and the variety which causes an obstruction in the floor of the prostate, where there is a collar or some deformity preventing the patient from emptying his bladder, and these are the cases for the Bottini operation. He believed the Bottini operation has a high place in prostatic surgery.

Retention of Urine.

Drs. Ferd C. Valentine and **T. M. Townsend**, New York, subsequent to analyzing the causes of retention, showed that the emergency is entirely within the general practitioner's field. They pointed out the method by which each kind of emergency must be met and the technic thereof.

DISCUSSION.

Dr. Lydston said the relation of this society to the general practitioner is largely educational. Only the specialist sees the result of injudicious work done by the practitioner in his efforts to relieve retention. He said there are still some physicians who think it perfectly proper to lubricate the catheter with the soap at the office sink. He thought more emphasis should be placed on the danger of complete and sudden emptying of the bladder after prolonged retention.

Dr. Shelbine, Texas, mentioned the case of a patient having lost the catheter which slipped back into the bladder. Suprapubic cystotomy was performed and the catheter recovered.

Dr. Guiteras thought the lithotrite might have been used for the recovery of the catheter.

Dr. Valentine said the case was of practical interest. He had three cases where he was sure the reflex swelling would take the catheter into the bladder very rapidly should it be released.

AMERICAN ACADEMY OF MEDICINE.

Twenty-eighth Annual Meeting, held in Washington, D. C., May 11, 12, 1903.

The President, Dr. Charles McIntire, Easton, Pa., in the Chair.

Drs. Helen C. Putnam, Edward Jackson and George G. Groff were appointed a committee to report on the teaching of school hygiene at the next annual session.

Time Allowance in the Combined Collegiate and Medical Course.

Dr. A. L. Benedict, Buffalo, stated that a large number of replies had been received to communications sent to colleges, medical schools and universities by his committee. Some conclusions drawn were that it will be impracticable for many years to insist on the basis of a bachelor's degree as a preliminary to a medical training; that it may be expected that all of the more densely populated states will have insisted on a full high-school education for medical students within a few years; that a combination collegiate and medical course of six or seven years will produce a higher average attainment than the admission of the high school and college graduates to the medical school on precisely the same basis; that the combination course is not to be considered as compromising the educational value of the college course or the technical value of the medical, provided, that a suitable arrangement of details is made; that the segregated medical colleges manifest the tendency to minimize the importance of mental training and broad culture and to exaggerate the importance of purely technical facts; that unless it be granted that the tendency to the destruction of the independent college and to the inferiority of the independent medical school is inevitable and desirable, voluntary co-operation and legislative control must be invoked in the interests of such institutions.

Results of the State Examinations for Medical Licensure in 1902.

Dr. Charles McIntire made a report, giving the results of examinations in all states arranged by colleges.

Dr. H. Bert Ellis, Los Angeles, Cal., read a paper on "The Necessity for a National Bureau of Medicines and Foods."

The Life and Education of Our Girls as Affecting Their Future.

Dr. James H. McBride, Pasadena, Cal., in a paper on this subject, urged the necessity of good physical development as a foundation for mental development. He referred to the necessity of girls knowing something of the duties of home life and of the responsibilities of motherhood. He stated:

> The mind is the highest expression of human life. Our ancestors shaped our bodies by their lives. Their lives afforded them exercise. We need to find something to develop our bodies now that our mode of living has changed. Especially true is this of woman, whose greater complexity and more delicate organism makes it important that she lay a good physical foundation.

Overstudy, unhygienic dress, and fictitious animation are common causes of nervous disorder and other forms of ill health in girls and women. The highest ideal for girlhood, he said, is thorough womanhood.

DISCUSSION.

Dr. S. A. Knopf, New York City, believed that the American women have improved in physical development very wonderfully in the last twenty-five years. In the better classes of society investigation would show that physically women had gained more, proportionately, than men; possibly this was true morally and mentally. On the other hand, in the lower classes of society, the development of women had been sadly neglected, particularly through the curse of child labor. This is particularly so in the eastern states. Regarding the education of children, he believed that the superintendents of the public schools should be educated to cut down the curriculum and to pay more attention to the physical development of the children.

The Teaching of Hygiene in the Public Schools.

The afternoon was devoted to a symposium on the above subject.

Dr. Walter L. Pyle, Philadelphia, read a paper entitled "The Teaching of Personal Hygiene." Dr. Pyle contended that what is needed is simple instruction by capable teachers in the proper care and use of the body, authoritatively based on the best available modern, anatomic, physiologic and hygienic data. The aim should be to give every man fundamental knowledge that will enable him to understand and if necessary formulate the requisite rules of health, and to distinguish scientific medicine from quackery. He strongly urged more literature and personal explanation in this direction from the medical profession. The instruction should be begun before habits of carelessness and indifference are formed. Teachers should be trained in the proper care and use of the human body in order to give this instruction.

Dr. George G. Groff, Lewisburg, Pa., presented a paper on "Physiology vs. Hygiene in Our Public Schools," which was read by the secretary. Dr. Groff said that anatomy and physiology should not be taught young children because the subjects are in the main beyond their comprehension; teachers are not prepared to teach the subjects; the impressions received by young children are unfavorable when anatomic structures and physiologic processes are displayed to them. Plain hygienic instruction can be readily comprehended without anatomy or physiology. Physiology as physiology he would not have taught below the grade of the high school, because teachers have no adequate knowledge of the subject; and because, until this time, pupils are not prepared for it. Personal hygiene is best taught to young children through incidental talks given at suitable times. Existing text-books need revision, he stated, in reference to loose generalized statements, inaccurate statements and statements actually false. Numerous examples of gross misstatements were cited.

The Teaching of Physiologic Breathing.

Dr. G. Hudson Makuen, Philadelphia, said it has been estimated that there are in the United States alone more than 300,000 stammerers, and that a study of this distressing affliction as manifested in several hundred cases has led him to the conclusion that its chief cause is faulty breathing in childhood. Still more serious is the result of faulty breathing on health and general development. Many grave diseases of childhood may be traced directly to the impoverished condition of the blood due to inadequate oxidation. The important factor is the unnatural and cramped position assumed by children in school. The importance therefore of establishing correct physical habits during school life can not be overestimated. He would have the teachers insist on the children taking correct positions at all times as a preliminary to physiologic breathing. Physical obstruction to normal breathing should be removed as early as possible. All breathing exercises are harmful when they are obstructed in the respiratory tract. As an examination of the eye is insisted on in the schools, so would he insist on an examination of the respiratory tract. It has been estimated that about 70 per cent. of people fail to use the nose in breathing at night, and in so doing fail to get the 20 to 40 per cent. of heat and the 60 per cent. of moisture in the respired air that should come from the nasal passages, and, moreover, they take into the throat countless germs that would otherwise find lodgment in the vestibules to the nostrils.

Dr. Makuen quoted the census of 1900 as showing that about 40 per cent. of the deaths occurring between 20 and 50 years were due to diseases of the respiratory tract. He is convinced that faulty breathing is an important factor in the causation of this great mortality, and that the percentage may be reduced by the scientific teaching of physiologic breathing.

Teaching of School Hygiene.

Dr. Helen C. Putnam, Providence, R. I., in the next paper, maintained that the head of the department of hygiene in public schools should have medical and liberal degrees, five years' private practice and at least two years' special study of pedagogics, gymnastics and school sanitation. The department should conduct medical inspection, supervise sanitation and teach hygiene in theory and practice. The staff of the head of the department should comprise inspectors who are qualified physicians; teachers of hygiene, college and normal graduates who took scientific electives; of physical training and "domestic science," from special schools. It is suggested that the department can be established by city authorities, though this would be less satisfactory than by private endowment. In the private endowment plan one advantage is a special committee, safe from political influence, to administer the funds.

Methods in Michigan Schools.

Dr. Victor C. Vaughan, Ann Arbor, Mich., reviewed the attempts made in Michigan to secure instruction in hygiene in public schools. Under authority of the State Board of Health a monthly sanitary bulletin is sent free to every teacher in the state. This plan has been found to work satisfactorily.

The Training of Teachers of Hygiene.

Dr. Thomas D. Wood, New York, maintained (in a paper read by Dr. Edward Jackson) that every teacher in the public schools should be a teacher of hygiene and the art of health, and should be in personality and conduct an example of rational living. There should be thoroughly trained special teachers of hygiene to supervise the instruction given in matters of health by the general teacher. The general teachers should be trained in the normal schools for this health instruction by course in biology, physiology, personal and school hygiene and sanitation.

DISCUSSION.

Hon. William T. Harris, U. S. Commissioner of Education, Washington, D. C., stated that with the matter of hygiene in the public schools in the hands of regular physicians great improvement would be brought about. The gymnastic exercises popular in the public schools he feels rob the brain of nervous energy and, if vigorous, can not be good for the child after a hard lesson. The only result of calisthenics under such conditions is to give a tendency toward nervous dyspepsia. The only aid in the teaching of hygiene in the public schools he felt must come from the medical profession.

Dr. S. A. Knopf, New York City, said practical hygiene could be taught a child of 4 or 5 years, in that it could be taught that it should not kiss its neighbors on the mouth, and that when it had dirty finger nails it should not scratch itself, and that a cut finger should be allowed to bleed, put under clean water and wrapped up. When the child gets older it should be taught not to expectorate on the floor and that all expectoration contains what are called pathogenic micro-organisms. In his own practice many tuberculous patients did not know what it meant to take a deep breath. In the teaching of school hygiene in New York they have experimented in having the nurse attached to the school, go to the home and teach the mother how to take care of a child sent to the school suffering with any skin disease. One practical lesson in hygiene taught the mother he thinks of more value than many to the children. In addition to the sanitary bulletin issued to the teachers mentioned by Dr. Vaughan, he would have leaflets on hygiene sent to the pupils.

Dr. F. H. Gerrish, Portland, said that if there were no teaching of hygiene at the present time it would be comparatively easy to institute a good method. The pernicious method now in vogue could be readily understood by an examination of some of the books recommended.

Dr. James H. McBride, in reference to faulty positions of school children, said that many a child seemed dull because he was not taught to sit up and keep his muscles in harmony with his mental attitude. He suggests that a school of hygiene for physicians might be of value.

Dr. W. R. White, Providence, thought the experiment described by Dr. Putnam an extremely practical one. He thinks the time is coming when the school physician will have his proper position, and that the instruction which the head of this department would give through his assistants to teachers, enabling them to distinguish early the symptoms of different diseases, would be of the utmost value in the saving of time and of public money.

Dr. A. L. Benedict, Buffalo, thought a sharp distinction should be made between hygiene and the teaching of hygiene. Both are important subjects and it is difficult to avoid confusing them.

Dr. Edward Jackson, Denver, believed that the teaching of hygiene by the wholesome, healthful life is the supreme object. It is not the teaching of hygiene as a special technical branch which deals with the periods of incubation of certain diseases or the particular way in which certain bacterium is transmitted, but the teaching of the healthful life; and, in these discussions, the personal hygiene, he thought, was too much lost sight of. The important thing in school hygiene is to have the supervisor of the right sort. While he does not think the present system of school hygiene altogether a hindrance, as had been indicated, he thought it a matter of shame to the medical profession that these laws had been framed, passed and enforced in nearly all the states by persons who had no intelligent comprehension of what the teaching of hygiene should be.

Dr. G. Hudson Makuen believes that the value of the gymnastic exercises is not alone in throwing the windows open and getting fresh air into the school room, not so much in the exercise of the muscles, but in the exercise of the mental faculty, the faculty of attention and of imitation. He believes that the calisthenic exercises have in them elements of psychical development not found in the average school work and study.

At 8 p. m., the president, Dr. Charles McIntire, gave his address on "Muck-Rake Methods in Medical Practice."

(*To be continued.*)

AMERICAN GYNECOLOGICAL SOCIETY.

Twenty-eighth Annual Meeting, held in Washington, D. C., May 12 to 14, 1903.

(*Continued from page 1447.*)

Myomectomy or Hysterectomy.

Dr. Joseph Taber Johnson, Washington, D. C., said the treatment depended on the size, variety and location of the tumor, as well as the size of the pregnancy. Myomectomy in favorable cases should be the operation of election. However, cases occasionally present themselves with such urgent symptoms as to require supravaginal hysterectomy as a life-saving operation. He described briefly successful operations of both varieties. He discussed the questions of abdominal and pelvic operations during pregnancy; also the propriety of inducing premature labor, as well as the policy of trusting to the *vis medicatrix naturæ*.

Pregnancy and Labor Complicated by Myomata.

Dr. George Tucker Harrison, New York, followed. No general rules can be laid down with reference to the treatment, as each case must be carefully studied in all its circumstances before recourse is had to operative intervention. The dangers of this complication of pregnancy as a cause of dystocia were formerly over-estimated. The plan of treatment during pregnancy, as a rule, is an expectant one.

Discussion on Fibroids, Etc.

Dr. Edward Reynolds, Boston, spoke of the treatment of large incarcerated fibroids, at or near term, in advance of the fetal head. He has seen ten such cases. No one of these tumors was smaller than the seventh month fetal head. In each instance the woman was delivered either normally or by forceps.

Dr. J. Duncan Emmet, New York, said there is no question but that certain myomata must be removed either by myomectomy or by the radical removal of the uterus, while there are other cases in which the tumors do not interfere with the course of pregnancy. He was glad one of the essayists had emphasized a preference for myomectomy rather than the removal of the uterus, for the reason that the latter is such a serious procedure in its after-effects, etc.

Dr. Wm. R. Pryor, New York, expressed himself in favor of conservatism in the treatment of fibroids associated with or complicating pregnancy. If the tumors are situated in the anterior wall of the uterus, and are very small, they would slide up over the pubes without much trouble. Even before the seventh month, while some of these tumors may seem to be an actual bar to delivery, they accommodate themselves by their softness to the situation. Subperitoneal fibroid tumors complicating pregnancy demand operation, as a rule.

Dr. Henry D. Fry, Washington, D. C., spoke of emptying the uterus, saying he thought the cases are rare where this procedure is called for. The treatment is either expectant or radical. Those tumors which indicate emptying the uterus are necessarily located in the lower uterine segment, and yet some of these occasionally rise in the pelvis and give very little or no trouble.

Dr. Walter P. Manton, Detroit, looked on cases of fibroid tumors complicating pregnancy as very rare. Personally, he has seen but six such cases out of approximately five or six thousand cases of labor in both private and hospital practice. In the majority of cases of interstitial submucous fibroids, abortion almost inevitably occurs between the third and fifth months.

Dr. Reuben Peterson, Ann Arbor, Mich., spoke of a case on which he had operated. The tumor was located in the lower uterine segment, and was of the interstitial variety. He did a myomectomy, the woman went on to full term and was delivered of a child.

Dr. George J. Engelmann, Boston, had twice seen the disappearance of fibroids following confinement.

The symposium was further discussed by Drs. Charles M. Green of Boston; Arthur W. Johnstone of Cincinnati; James Clifton Edgar of New York City, and the discussion closed by the essayists.

Combined Bisection of Tumors and Uterus, with Enucleation of the Former, in Abdominal Hysterectomy for Large Fibroid Tumors.

Dr. George H. Noble, Atlanta, Ga., read a paper entitled as above. In case of large fibroid tumors in the body of the uterus the author recommends bisecting the tumor, bisecting the uterus and then enucleating the bisected tumor. In intraligamentous tumors the uterus should be bisected, the capsule of the tumor penetrated from the cavity of the uterus and the tumor enucleated from its capsule.

The advantages of this method are: Saving of time, prevention of hemorrhage, increased working space, easy manipulation, accessibility to the blood supply in the deep pelvis, and freedom from liability of injury to the ureters and uterine arteries.

Dr Noble then discussed "The Enucleation of Intraligamentous and Postperitoneal Fibroid Tumors in the Deep Pelvis." He stated that he had received a reprint from Dr. Pryor, in which Pryor anticipated him in the treatment of intraligamentous tumors or postperitoneal fibroids in the deep pelvis. As the principle is the same, and both of them only differ in technic, the essayist indorses it. Intraligamentous tumors are partially enucleated by penetrating their capsules from the cavity of the uterus after bisecting the organ. They should be turned out with the fingers and morcellation forceps, then drawn up and rotated outward as described. The portion of the tumor attached to the capsule everts the latter as it is drawn out of the abdominal incision, and often to such a surprising extent that it may be included in the ligature placed around the upper border of the broad ligament. In this way the capsule in some cases may be entirely removed, and in others only cut away, and, if within the ligature of the pedicle, avoids the necessity of suturing the edges of the capsule. He said that Dr. Pryor did complete enucleation of the tumor and sutured the capsule, while he partially enucleated the tumor, utilizing its attached portion to pull up the capsule, transfix and tie off, in part or entire, with the ligature of the broad ligament.

The Relation and Corelation of Gynecologic and Nervous Affections.

Dr. Chauncey D. Palmer, Cincinnati, spoke of this relationship from two standpoints: (1) What influence do female pelvic diseases have in the induction of nervous disorders? (2) What affections of the female pelvic organs arise from nervous derangements?

He ruled out any thought of the occurrence of any organic, so-called structural, lesions of the nervous system, as resulting, unless indirectly and quite remotely, from pelvic diseases. The morbid changes to which reference was made were hysteria, neurasthenia, neuralgia, chorea, epilepsy, hystero-epilepsy, certain paralyses, migraine, convulsions of certain kind, including tetanus, also mental aberrations and vasomotor changes.

While many hysterical women have no anomaly of the sexual organs, a certain proportion of them have some imperfection in the development of their sexual apparatus, especially the uterus. Hence, the justifiability of an oöphorectomy in some such cases. Should the sexual organs be diseased in hysterical women, one could not say that the hysteria was secondary. Psychical causes are at work which are more potent than the local disease.

Errors in diet, in general hygiene, in lack of rest, and in various indulgences of the mind and body in girlhood, lead to physical anomalies and give rise to abnormal mobilities of the nervous system. The functions of ovulation and menstruation play more than the ordinary rôle in the inauguration of nervous phenomena.

The author spoke of cases of insanity having been promptly relieved by gynecologic operations. Likewise, insanity had immediately followed operations. Such sequelæ were probably more common than after other operations.

In the treatment of women for the special diseases of their sex there is too much of a tendency to place undue stress on real or supposed lesions of her reproductive organs. This is particularly true in reference to some so-called ovarian affections. Gynecology of to-day would not amount to much without an appropriate surgery, but indiscreet surgery, like overmedication, may be an abuse. Every theory in medicine must be the outgrowth of an extended experience. "Knowledge comes, but wisdom lingers."

The Etiology, Pathology and Treatment of Puerperal Sepsis.

Dr. Hiram N. Vineberg, New York, contributed this paper. Severe sepsis may be caused by a variety of pathogenic germs. The variety of germs found in the uterine discharge in a given case is no criterion of the severity of the case, and forms no safe guide as to prognosis or as to the treatment to be adopted. Bacteriologic examination of the blood is of little value, either from a prognostic or therapeutic standpoint. The treatment of puerperal sepsis must be based chiefly on the clinical history and physical signs of each individual case. Wounds or infection in the perineum, vagina or cervix are to be treated on the general surgical principles of irrigation and drainage. Curettage is indicated where there are evidences of placental decidual residue in the uterus independent of the variety of bacteria that may be found in the uterine cavity. In those rare cases in which adherent and sloughing placental tissue can not be removed, either with the sharp curette or fingers, hysterectomy is indicated, provided the patient is not already moribund. Hysterectomy is also indicated in cases of septic endometritis or infection of the placental site, so long as the infection is still limited to the uterus, and when the symptoms steadily grow worse in spite of uterine irrigation, with or without curettage, and appropriate hygienic stimulating treatment.

In abscess of the uterus the abdomen should be opened, and, when feasible, the purulent foci should be drained and the uterus preserved. If the uterus be studded with small abscesses hysterectomy is indicated. The abdominal is to be preferred to the vaginal route for hysterectomy. If the infection has passed from the uterus into one or other tube, and has set up a violent grade of inflammation, the abdomen should be opened and the infected tube removed before a general peritonitis develops. When the infection has passed through the uterus, and has set up a general peritonitis, a case might occasionally be saved by a timely abdominal section and drainage. In cases of parametric exudates the treatment should be conservative, and surgical intervention is indicated only when there are evidences of pus formation. In obscure cases in which the pathologic lesion can not be determined, and the symptoms are steadily growing worse, it may be advisable to open the abdomen to search for a hidden purulent focus, or for a circumscribed slough of the uterus. The procedure proposed by Trendelenburg, and executed by him and others, of ligating the pelvic veins when they have become infected and thrombosed, is worthy of further trial.

DISCUSSION.

Dr. Wm. R. Pryor, New York City, took issue with the essayist in regard to the significance of certain pathogenic germs. In mild cases of puerperal sepsis, very rarely is the streptococcus present, while in the severe ones streptococci are found. In the mild forms of the disease many other kinds of germs are found, chiefly staphylococci and saprophytic bacteria. The form of puerperal sepsis which demands careful attention is due to the streptococcus.

Dr. Edwin B. Cragin, New York City, related his experience at the Sloane Maternity. In this institution infection occasionally occurs, because cases are taken undelivered, no matter whether they have been handled by midwives or by beginners. Women are admitted whether they are just in labor or whether they have been in labor for several days. Occasionally a patient has been lost from puerperal infection, although pathologist and bacteriologist were unable to find the streptococcus. A number of severe cases have been observed in this maternity in which a variety of bacteria were found in the uterus. In the management of puerperal sepsis he emphasized two points: First, to make sure the uterus is emptied. Second, in making sure that it is emptied, do just as little damage to the inside of the organ as possible.

Dr. J. Whitridge Williams, Baltimore, laid stress on the value of bacteriologic examinations of the uterine lochia and of the blood. In many cases there is no definite indication for treatment from such examinations, yet there is no doubt in his mind that important and valuable information as to the condition of the patient can be elicited in this way, more particularly by examining the blood. He has seen but two cases of puerperal sepsis in which he feels operation was distinctly called for.

Dr. Matthew D. Mann, Buffalo, N. Y., spoke of gonorrheal infection in connection with the puerperium. Recently he saw a patient in consultation who had been sick for more than a week when she was first observed by him. Her temperature reached 111 before death. She had been having a temperature of from 107 to 108 for a number of days. Pulse was 120. Examination of the discharges by competent bacteriologists showed a pure culture of the gonococcus. There was no other germ present in any of the secretions. He thought the infection would localize itself and the woman would recover; but the joints and heart became affected and the patient died.

Dr. G. Gill Wylie, New York City, said there can be no question but that surgical intervention is indicated in some of the severe cases of puerperal sepsis. Of his first nine cases, which were treated at the Bellevue Hospital some twenty years ago, seven were dealt with locally and two surgically. He believes the uterus should be emptied in every case of severe streptococcus infection.

Dr. Edward P. Davis, Philadelphia, in speaking of hysterectomy in cases of puerperal sepsis, stated that this operation has nothing definite to support it except in rare cases of adherent placenta. A method which yields good results, where irrigation has failed, consists in opening the abdomen and inspecting the uterus, tubes and ovaries, freeing adhesions, etc., and, if there is a collection of pus in the tubes, drainage by means of iodoform gauze carried through into the vagina, separating the organs from abnormal adhesions.

Dr. Malcolm McLean, New York City, referred to the curette as a dangerous instrument in cases of puerperal sepsis in the hands of the average general practitioner. Emptying of the uterus is an absolute necessity in some cases, especially where there is evidence of putrid absorption, with chill and sudden high temperature.

Dr. Henry D. Fry, Washington, D. C., said the practice at the Columbian Hospital, where a large number of maternity cases were observed, was first to thoroughly clean out the uterus, particularly if the patients were seen at the beginning of sepsis and it was confined to the uterine cavity. After having taken a culture, active treatment of the uterus is suspended until the result of the culture is made known. If there are retained pieces of placenta, and blood clots, accompanied with a foul odor, producing infection, the indication for cleaning out the uterus is clear. On the contrary, if the culture showed streptococcus, staphylococcus, colon bacillus, or gonococcus, the uterus was left alone. In cases of streptococcus infection he believes the use of the curette does a great deal of harm, in that it breaks down the protective zone of inflammatory tissue, which is thrown out by Nature and which causes ultimately a general systemic infection.

Dr. Herman J. Boldt, New York City, said experience has taught him, so far as the treatment of puerperal sepsis is concerned, that a bacteriologic examination of the secretions from the vagina or from the uterus, or a bacteriologic examination of the blood, furnishes no indication whatever for treatment, because there is usually a mixed infection, both streptococci and staphylococci being found in the secretions of the uterus and vagina. Such patients frequently manifest mild clinical symptoms, although operative intervention is not indicated. In all cases that come under his care, examinations of the secretions and of the blood are invariably made, and in patients who show bacteria in the blood, even a pure staphylococcus infection, the general condition of the patient does not seem to indicate the need of surgical intervention, consequently they are left alone, and recover. On the other hand, many patients show absolutely no bacteria in the blood, yet they die, so that, as the result of accumulated experience, bacteriologic examinations of the secretions and of the blood of such patients do not give a definite clue as to the indication for treatment.

Hysterectomy is of no avail in the severe cases of puerperal sepsis, as the patients die within a few days.

Dr. Seth C. Gordon, Portland, Me., thinks surgical treatment is undertaken too early in some cases of puerperal sepsis. If there are abscesses of the fallopian tubes, they should not be opened until one is quite sure that he can make a straight incision from the vaginal vault into the abscess cavity, without having any doubt as to whether pus is limited to the top of the vaginal wall. Every time an abrasion is made in the uterus or vagina with the curette or knife, he thinks a new avenue of infection is opened up, and causes, in many cases, a great deal of harm.

Dr. H. G. Wetherill, Denver, referred to the Carosso method of treatment of puerperal sepsis, saying its value was unquestionable. This method has been advocated particularly by Dr. Edward J. Ill, of Newark, N. J.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Seasickness.

According to an abstract in the *Indian Med. Record,* railway and seasickness is due to the rapidly changing focus, occasioned by the eyes closely following the apparent approach and withdrawal of objects. It was observed that by closing one eye the usual unpleasant sensation was prevented. On sea the sickness is likewise produced by watching the top of the waves, and this, together with the movement of the ship, which, according to the author, complicates very much the mechanism of focusing produces an intersection of focus curves, and thus causes seasickness. Covering one eye abolishes all these curves and relieves the nervous condition. So lying on the back serves a similar purpose because the eyes are then focused at a definite and fixed distance. Lying on the side is not so good because of the greater probability that the focus will be changed.

Calcium Chlorid in Scrofula.

Lilgois, as noted by the *New York Med. Jour.*, states that calcium chlorid is of value in the treatment of scrofula. The salt contains more than one-third of calcium, is of great benefit to the osseous system, in scrofula, which is poor in mineral matter. The following combinations are recommended:

℞.	Calcii chloridi			
	Calcii phos., āā	gr. viiss		50

M. Ft. chart. No. i. Sig.: One such after the mid-day and evening meals; or:

℞.	Calcii chloridi	ʒi	4	
	Aq. destil.	℥xii	360	
	Syr. Corsican moss	℥iss	45	

M. Sig.: To be taken in three doses during the day; or:

℞.	Calcii chloridi	ʒii-ʒiiiss	8-14	
	Aq. destil.	℥xvii	510	
	Syr. gentianæ	℥ii	60	

M. Sig.: One or two tablespoonfuls daily; or:

℞.	Calcii chloridi	gr. lxxv	5	
	Syrupi	℥xiii	390	
	Aq. menth. pip.	℥iiss	75	

M. Sig.: One tablespoonful before each meal.

The calcium should be continued for weeks, and in some cases the treatment should be prolonged for months.

Gonorrhea.

The following outline of local treatment of gonorrhea, according to the *New York Med. Jour.*, is recommended by Z. Rojos de Molina:

℞.	Zinci sulphatis	gr. iss		09
	Aquæ destil.	℥i	30	

M. Sig.: Use as an injection after each urination.

The author prefers the foregoing combination to potassium permanganate, protargol or other similar preparations. In order to subdue the pain after each micturition, the patient is directed, after each urethral injection, to inject a small amount of the following:

℞.	Zinci sulph.	gr. 3/10		018
	Cocainæ hydrochlor.	gr. iii		20
	Aquæ destil.	ʒv	20	

M. Sig.: As an injection.

Quinin Salicylate.

Moore, in the *Practitioner*, states that quinin salicylate is of great service in the treatment of rheumatism. In diphtheria, in addition to the administration of antitoxin, he recommends the following as a spray to the throat:

℞.	Resorcin	gr. x		65
	Aquæ	℥i	30	

M. Sig.: Locally as a spray.

He also gives quinin salicylate in 3 to 5 grain (.20-.30) doses, according to the age. It is of great service also in influenza, pneumonia, typhoid fever, scarlatina, erysipelas and measles. He also prescribes it in herpes zoster to relieve the pain and in chlorosis as a gastro-intestinal antiseptic and disinfectant.

Alopecia Circumscripta.

Shoemaker, in *Med. Bul.*, states that persons troubled with alopecia circumscripta generally require constitutional treatment by means of diet and proper medicine.

The following combinations are advised by him:

℞.	Syr. ferri lactati	ʒii	8	
	Ext. malti diastasic	℥vi	180	

M. Sig.: One dessertspoonful three times a day, after meals. Locally the following:

℞.	Sulphuris sublim.	ʒi	4	
	Olei eucalypti	m. x		65
	Acidi salicylici	gr. x		65
	Ung. zinci oxidi	℥i	30	

M. Ft. ung. Sig.: Rub into the affected spots well twice a day.

Acute Parotitis.

E. Grande, in *Sem. Méd.*, advocates the employment of guaiacol in the treatment of epidemic parotiditis. He applies it locally in the form of an ointment of 5 per cent. strength and repeats the application four or five times during the day, followed by a thick covering of absorbent cotton. The swelling rapidly subsides and the pain on chewing and swallowing is likewise decreased. He is of the opinion that the guaiacol exerts a local antiseptic action as well as an analgesic condition. No eczematous condition follows the application to the face as is frequently the case when applied to the scrotum.

Eczema.

In chronic eczema the same author recommends, after correcting the cause, the following outline of treatment:

℞.	Vini antimonii	ʒiii	12	
	Tinct. nucis vom.	ʒiii	12	

M. Sig.: Ten drops four times a day, gradually increased to twenty drops four times a day.

The antimony, it is believed, allays the congestion and promotes the elimination.

Externally the following is used:

℞.	Chloralis hydratis	ʒss	2	
	Camphoræ	gr. x		65
	Acidi carbol.	m. xx	1	30
	Ung. zinci oxidi	℥i	30	

M. Ft. unguentum. Sig.: Apply locally night and morning.

Hemorrhoids.

Dr. J. P. Tuttle, in *Interstate Med. Jour.*, favors the treatment of hemorrhoids by means of injection, using a moderately strong solution of carbolic acid in order to set up inflammatory induration, which will cut off a portion of the circulation to the growth and result in gradual atrophy. He claims, with the proper antiseptic precautions, that there is no danger of sepsis, abscess formation or sloughing. He recommends the following combination to produce the results above stated:

℞.	Acidi carbol.	ʒii	8
	Acidi salicylici	ʒss	2
	Sodii biboratis	ʒi	4
	Glycerini q. s. ad	℥i	30

M. Sig.: Five minims to be used as an injection into the hemorrhoid.

At the end of one week, as a rule, the remaining tumors may be similarly treated.

In the varicose type of external hemorrhoids prompt evacuation of the bowels should be obtained by administering a cold enema, after which the following ointment should be applied:

℞.	Ung. acidi tannici		
	Ung. belladonnæ		
	Ung. stramonii, āā	℥i	30

M. Sig.: Apply freely to the affected parts.

Dandruff.

The following is recommended by Merck's Report:

℞.	Resorcin	ʒi	4	
	Tannoformi	ʒi	4	
	Acidi salicylici	gr. v		30

M. Ft. chartula. Sig.: Dissolve the powder in three ounces of alcohol just before use, to which is added one ounce of water and the entire amount filtered; or:

℞.	Resorcin	ʒi	4
	Acidi borici	ʒss	2

M. et fiat chartula. Sig.: Dissolve in four ounces of water just before using.

Rachitis.

Burney Yeo, in *Clin. Ther.*, recommends, in the treatment of rickets, that too much carbohydrates should not be given to hand-fed children. The milk used should contain its full proportion of cream. He recommends cod-liver oil made into an emulsion with lime water flavored with sugar of milk, giving ten or fifteen drops at a dose. The pulp of raw meat is also of great service, giving as much as two ounces (.60) daily, varying the amount according to the age. In feeding older children milk puddings may be served made out of entire wheat flour, or sandwiches or raw meat pulp, meat juices and broths, eggs beaten up with milk, and the juice of fresh fruits may be added. The proper attention must be given to hygienic surroundings, sunshine, etc.

Rachitic children are more susceptible to pneumonia and other pulmonary complications and consequently they must be warmly clad with woolens and a woolen bandage applied to the abdomen. The clothing must fit loosely in order not to restrict the respiratory movements or the movement of the limbs.

In the anemic cases Yeo recommends the syrup of the iodid or citrate of iron and ammonia. Arsenic is also of service in these cases. If nervous complications arise the following mixture may be given as required:

℞.	Sodii bromidi	gr. xv-xx	1.-1.30	
	Chloralis hydratis	gr. viii		50
	Aq. cinnamomi	℥i	30	

M. Sig.: One teaspoonful as necessary.

The following combinations, as employed by Billroth, are recommended by the author for the constitutional treatment:

℞.	Ferri carb.		
	Ferri lactatis		
	Calcii phos.		
	Sacchari lactis, āā	ʒiss	6

M. chart. No. lx. Sig.: One powder two or three times a day; or:

℞.	Olei morrhuæ		
	Syr. calcis lactophos.		
	Liq. calcis, āā	m. xv	1

Sig.: At one dose; to be repeated three times a day—for a child of one year.

The following, containing phosphorus, are frequently prescribed:

℞.	Phosphori	gr. i		06
	Alcoholis	ʒv	20	
	Spts. menth. pip.	m. x		65
	Glycerini q. s. ad	℥ii	60	

M. Six to twelve drops three times daily after meals; or:

℞.	Phosphori	gr. 1/7		0085
	Saccharin	gr. lxxv	5	
	Ess. limonis	m. ii		12
	Ol. morrhuæ	℥iiss	105	

M. Sig.: One teaspoonful three times a day in milk.

Medicolegal.

Alteration of Unauthorized Temporary License.—In the case of Volp vs. Saylor and others, State Board of Medical Examiners, it appeared that, in 1891, the Oregon State Board of Medical Examiners issued what was intended to be a temporary license only, certifying that Heinrich Volp, having passed a satisfactory examination in medicine and surgery, was authorized to practice same until a certain date, or, in other words, for six months. The secretary testified that the board had adopted the practice of giving temporary permits so that the applicant, if unsuccessful, could still earn a livelihood, with the understanding that he again submit himself for an examination at the expiration of the period fixed in the certificate. On the trial, however, it was stipulated that the board had no power to issue a temporary permit or license. But because the board of examiners adopted an irregular and unauthorized practice, and issued a permit or license, using the form of a regular certificate, but limiting its duration, the Supreme Court of Oregon does not consider that it followed, as was argued, that such board issued and delivered an ordinary or regular license, unlimited in its scope, and therefore valid. It says that to construe such an act as the board's into absolute regularity, and the permit of six months' duration into a license regular in form and unrestricted as to the time of the operation, would be to contort an irregular and void proceeding into one of due regularity and perfect legal efficacy. The erasure of that portion of the certificate intended as a limitation could not, by any rule of ethics or practice, either in law or morals, operate to admit the holder as a regular practitioner of medicine and surgery. The fact that it was certified that he had passed a satisfactory examination could not aid him, as the certificate by its very terms limited the time the board intended he should exercise the privilege accorded, and the suggestion that the board was precluded from showing that the examination was unsatisfactory was without relevancy in the argument. He may have been entitled to a full license on such a showing, but he did not get it, and his act of changing the certificate received could not operate as an act of the board granting that which he applied for. Nor does the court accede to the contention that his license could be revoked except for unprofessional or dishonorable conduct, and that his act in changing the certificate, and thus procuring his name to be entered in the register, did not come within the meaning of such terms as declared by the act of 1895, which provided that all persons who had been regularly licensed under theretofore existing laws of the state, and had complied with the provisions thereof, should be taken and considered as licensed physicians under this act. It says that this proceeded on the assumption that he was regularly licensed, and that he was then entitled to practice by reason thereof. But he had no such license to revoke. The record he caused to be made gave him none, but it falsely showed that one had been regularly issued to him, and it was to get rid of this record that the board took action. What the board really did was to vacate a void record. Furthermore, the court holds that, where the record is admittedly fraudulent, as it was here, a court of justice will not intercede to reinstate it, even though it was vacated without notice to the party affected by the order. If the court could see that the party had been deprived of any substantial right without an opportunity to be heard, the case would be different; but he was insisting on a privilege vouchsafed to him by a license or record which he conceded to have been obtained through his own wilful and fraudulent act, and the court would not thus intercede to permit him to enjoy the fruits of his own wrong.

Compulsory Vaccination and Revaccination Law Upheld.—The Supreme Judicial Court of Massachusetts holds constitutional, in Commonwealth vs. Pear, Section 137 of Chapter 75 of the Revised Laws of that state, which provides that "The board of health of a city or town, if in its discretion it is necessary for the public health or safety, shall require and enforce the vaccination and revaccination of all of the inhabitants thereof, and shall provide them with the means of free vaccination. Whoever, being over 21 years of age and not under guardianship, refuses or neglects to comply with such requirement, shall forefeit five dollars." It says, among other things, that, so far as it is aware, all courts that have considered the subject have recognized the right of the legislature to enact laws founded on the theory that vaccination is important as a preventive of smallpox, and to impose restrictions, during an epidemic, on persons who have not been vaccinated. There are some cases in which it has been held that the statute did not go far enough to authorize the restrictions which the authorities sought to impose. But these assume that the legislature may interfere with the exercise of the ordinary rights of individuals if they are not vaccinated when smallpox is prevalent. Legislation requiring vaccination, or authorizing some local board to require it, as a prerequisite to attendance at school, has been sustained whenever called in question. Legislation requiring vaccination is mentioned by the Supreme Court of the United States as a proper exercise of the police power in Lawton vs. Steele, 152 U. S. 133-136. Statutes substantially the same as the one in this case have been sustained, after careful consideration, by the highest courts of Georgia and North Carolina. The views of the party here refusing to be vaccinated could not affect the validity of the statute, nor entitle him to be excepted from its provisions. He made some eleven offers of proof of alleged injurious or dangerous effects of vaccination, but the only competent evidence that could be presented to prove these propositions was the testimony of experts giving their opinions. It would not have been competent to introduce the medical history of individual cases. Assuming that medical experts could have been found who would have testified in support of these propositions, and that it had become the duty of the judge to instruct the jury as to whether or not the statute was constitutional, he would have been obliged to consider the evidence in connection with facts of common knowledge, which the court will always regard in passing on the constitutionality of a statute. He would have considered this testimony of experts in connection with the facts that for nearly a century most of the members of the medical profession have regarded vaccination, repeated after intervals, as a preventive of smallpox; that, while they have recognized the possibility of injury to an individual from carelessness in the performance of it, or even in a conceivable case without carelessness, they generally have considered the risk of such an injury too small to be seriously weighed as against the benefits coming from the discreet and proper use of the preventive; and that not only the medical profession and the people generally have for a long time entertained these opinions, but legislatures and courts have acted on them with general unanimity. If this party had been permitted to introduce such expert testimony as he had in support of these several propositions it could not have changed the result. It would not have justified the court in holding that the legislature had transcended its power in enacting this statute on their judgment of what the welfare of the people demanded. The theoretical possibility of an injury in an individual case as a result of its enforcement does not show that, as a whole, it is unreasonable. The application of a good law to an exceptional case may work hardship. Naturally, there would be regard to temporary conditions, if they became important, as to the time and manner of its enforcement. If a person should deem it important that vaccination should not be performed in his case, and the authorities should think otherwise, it is not in their power to vaccinate him by force, and the worst that could happen to him under the statute would be the payment of the penalty of $5. The contention that the statute works unequally, in making an exception of minors and persons under guardianship, is not well founded. It only limits the liability to a penalty for neglect of the requirement to persons who have a right to control their own conduct.

2. Appeared in The Journal of May 9, p. 1277.

3. **Cholelithiasis and Pancreatitis.**—The relation of these two conditions has only been lately a *matter of consideration* by the profession, and yet there are good reasons to assume its possibility. The pancreatic and common bile ducts have a common opening into the duodenum and the obstruction of the one may also be the obstruction of the other. Wiener discusses the subject and the literature, reporting a case of his own. He says from a careful study of 33 cases reported of pancreatitis associated with cholelithiasis, we are forced to the conclusion that in many there is a relationship between the two conditions. In a few cases the autopsy showed the duct of Wirsung occluded by gallstones. In one case, that of Dieckhoff, a biliary calculus had actually found its way into the pancreatic duct. Other cases point in the same way, and it is fair to assume, he holds, that in some instances where the offending calculus was not found, it had already escaped into the bowel. Fortunately the anatomic conditions are often unfavorable to occlusion of the duct of Wirsung or we would have many more cases of acute pancreatitis from gallstones. The author's case was saved, not because of an early correct diagnosis, but because of an early exploratory incision, and this, he thinks, is the crux of the whole problem in the prevention of these conditions.

7 *Differential Diagnosis in Diseases of the Gall Bladder and Ducts. George E. Brewer.

6. This article appeared in The Journal of May 9, p. 1284.

7. **Diseases of the Gall Bladder and Ducts.**—Brewer goes into detail as to the significance of various symptoms of gall-bladder and gall-duct diseases. He remarks in conclusion that it is well to remember the following facts derived from the best authorities:

Gallstones are rarely found in young subjects; according to Schroeder only 2.4 per cent. occur in individuals under 20 years of age. The same author states that 20 per cent. of all female, 44 per cent. of all male autopsies show the presence of calculi in the gall bladder. Ninety per cent. of the women have borne children. Gallstones have been known to escape from the biliary passages into the alimentary canal by ulcerative processes, and to produce intestinal obstruction without giving rise to pain or any other symptom until the evidences of bowel obstruction appear.

In common duct stone the calculus is found in 67 per cent. of the cases in the duodenal extremity, in 15 per cent. in the hepatic extremity, and in 18 per cent. in the middle portion of the duct (Robson).

One-half of all cases of common duct obstruction only are due to stone (Robson).

In 70 per cent. of the cases of obstruction located in the neck of the gall bladder the pain is referred to the right subscapular region, in 10 per cent. to the left subscapular region, and in 20 per cent. to the precordia, sternum, right subclavicular region or neck (Murphy).

The temperature chart in biliary infection is characterized by angularity rather than by curves, and by more or less prolonged periods of complete intermission (Murphy).

Jaundice is absent in from 80 to 90 per cent. of all operative cases of gall bladder or duct disease.

Jaundice preceded by colic is practically always due to stone; jaundice without pain is practically always due to inflammation or new growths of the ducts, or to outside pressure.

The bile in all cases of cholelithiasis should be regarded and treated as an infected secretion.

During the presence of a calculous jaundice, the sudden occurrence of acute epigastric pain, muscular rigidity, nausea, vomiting and collapse, without leucocytosis, strongly suggests acute pancreatitis occasioned by the presence of a stone in the diverticulum of Vater (Murphy).

10 *Notes on Blood Pressure in Man. (To be continued.) S. S. Goldwater.
11 Some Recent Advances in Medical Therapeutics. Thomas E. Satterthwaite.

9. **Fracture at the Base of the Skull.**—The presidential address before the New York Neurological Society by Bailey reviews the symptoms and outcome of fractures of the basis cranii. He goes over the various clinical symptoms relating to the special cranial nerves, finding pupillary abnormalities one of the commonest symptoms, injury of the motor nerves of the eye frequent and that of the facial nerve most frequent of all. Conditions of paralysis, changes of reflexes, mental symptoms, etc., are also remarked on. The immediate prognosis is bad; fatal results may be looked for in more than one-half the cases. The ultimate prognosis, if not immediately mortal, is somewhat better. He thinks the mental condition in the majority of cases is restored. In some cases there is a certain amount of irritability and change of character and in a few cases permanent mental impairment. There are but a comparatively small proportion of cases in asylums with a record of fracture of the base of the skull as a cause, and he says it seems to be an entirely unimportant cause of mental disease. Fractures of the base can hardly be compared with those of the vault with direct involvement of the cortex in the latter. The physical symptoms also seem to be largely relieved, if not cured, in many cases where death does not immediately follow the injury.

10. **Blood Pressure.**—Goldwater has examined the question of blood pressure in man, finding it varying from 250 or 255 mm. as the extreme to only about 40 mm. as the lowest. He discusses at length the conditions of blood pressure under special conditions, like pregnancy, the puerperal state, as producing changes in the blood pressure and the effect of mental effort. The fact that blood pressure appears to be raised in insanity during the periods of depression is discussed, emphasizing a further study of the relations existing in healthy individuals between depressing emotions and intravascular tension.

16 Gastric Carcinoma Associated with Hyperchlorhydria and with Attacks of Stupor. Norman B. Gwyn.
17 Foreign Bodies in the Bladder. Swithin Chandler.

13. **Tumors of the Breast.**—Hutchinson first notices Paget's eczema, in regard to which he remarks that the supposed parasites are, in his opinion, only the results of epithelial degeneration. As regards cysts in the breast, 80 per cent. of them are true retention cysts with milky contents, and the majority of cases require but simple tapping. In the remaining 20 per cent. the cysts are multiple and due to fibrous degeneration of the organ and, unlike retention cysts, situated usually in the periphery or circumference of the breast. He recommends an exploratory incision in case of retention cyst simulating cancer, holding that it will not do harm. Of course, the knife should be laid aside and disinfected after doing the incision. In fact, he says the surgeon should invariably make a cut into the substance of any supposed cancer. As regards excision of adenomata and cysts, he offers the following practical point, that in sewing up the incisions the stitches must be carried down to the bottom of the wound on either side, or else a bloody cavity will be very apt to form and delay healing as well as alarm the patient. The rare involution cysts, especially of the periphery, he thinks, in most cases would be better left alone. The most important point in differentiating retention cysts from carcinoma is, he holds, adhesion to the skin and its redness and dimpling in the latter. If the disease has long existed, of course there will be retraction of the nipple. Cachexia is the poorest sign of all and the least important. As regards excision of the breast, he says when you wish to obtain primary union you should not carry the incision through the middle of the axilla. Make it not through the center of the axilla, but up over the pectoralis major, right away from the area of the large sebaceous glands. If the scirrhus goes anywhere near the pectoralis major, remove the lower half of that muscle. Whether or not the pectoralis minor should be removed depends on the conditions, but access to the summit of the axilla is perhaps more free if it be excised. Avoid drainage tubes; wounds do not heal so well with them. Never tie the arm to the chest, but always bandage with it away from the side, to avoid subsequent stiffness. As regards the clearing out of the glands which are adherent to the axillary vein, he thinks it is better to dissect them out rather than to cut the vein boldly and tie it some inches higher up. For, by tying the vein, you may have persistent edema of the arm. The mortality of complete operations in his hands has not been over 3 or 4 per cent. His figures agree very well with those of Mr. Butlin at St. Bartholomew's and of Barker of the University College Hospital. The axilla should be cleared in every case, since in three out of four cases we find secondary deposits there. As regards secondary deposits of scirrhus, they are present mostly in the liver and next in the pleura and lungs and last in the pericardium, other breast, peritoneum, etc. The only frequent non-cancerous condition in patients dying from cancer of the breast is pleurisy. Oöphorectomy he considers as practically of very little value. There is no safe time limit for cure; as regards recurrence, he thinks the more experience one has the more one is encouraged to operate.

15. **Tetanus.**—Norris gives an analysis of 57 cases of tetanus from the records of the Pennsylvania Hospital, including all the cases treated there between 1874 and 1903. A curious thing is the complete absence of cases of tetanus between 1886 and 1893 which can not be accounted for. The mortality is largest in the warm months, August, September and October, and least in the colder part of the year, with a total average mortality of 85 per cent. Thus temperature seems to play a part, though the Fourth of July casualties, of course, account for a portion of the hot weather cases. The mortality is greatest in cases from wounds of the head and neck, 100 per cent. in the figures here given, and least in cases of the trunk and mixed injuries; there was only one case of injury of the trunk reported followed by tetanus. The heaviest mortality, according to age, was in the very early years and in

advanced life, nearly 100 per cent. in both, though the figures are small, only 5 of the former and 3 of the latter. The greatest number of fatalities occur in the early part of the disease. It would also appear from the table that the longer the incubation the less the mortality, though, of course, the insufficiency of statistics prevents thorough conclusions. Cases of punctured wound seem to be specially liable to produce the disease, and burns perhaps the least liable. The condition of the urine was noted in only 17 cases, but is interesting from the fact that the average specific gravity was 1.026. No definite relation could be established between the severity of the attack and the outcome of the urine analysis. The first symptoms were usually pain and stiffness in the back of the neck. Fever was present in nearly all of the cases where the temperature was recorded, and steadily increased to the end. Delirium is said to be a common symptom in alcoholic subjects and was recorded eight times. As regards treatment, the symptomatic is credited with 87 per cent. of mortality, carbolic acid treatment, according to the Bacelli method, 7 cases with 85 per cent., and antitoxin with 66 per cent. Though the latter was only employed in three cases, one of them recovered. He concludes his article by saying the following facts should be remembered in connection with the treatment of tetanus:

1. That tetanus toxin is found mainly in the nervous tissues; that, once united with these, antitoxin is powerless in its action on already affected cells.
2. That antitoxin is harmless, but deteriorates rapidly; therefore, it should be procured freshly and administered in continuous and large doses with the hope of immunizing the intact nerve cells.
3. That all cases of wounds in which there is a possibility of tetanic infection should receive prophylactic injections of antitoxin.
4. That local treatment is of great importance, hence the infected area should be excised; when this is impossible, extensive disinfection, preferably with carbolic acid, should be carried out; furthermore, that, as Behring has shown, antitoxin is of benefit locally as well as systemically.
5. That every effort should be made to maintain the nutrition of the patient, for Castronuovo has demonstrated that antitoxin is of no value in tetanic animals which have been starved.

24 The Duties and Responsibilities of Trustees of Public Medical Institutions. W. W. Keen.

18. Pruritus Vulvae.—Hirst remarks that the treatment of this condition is one of the unsolved problems. Two surgical methods are available: 1. That of exclusion of the affected part as proposed by Schroeder, and the other, resection of the nerve. Hirst discusses the advantages and disadvantages of this method, but while report of a case is stated in the title, his paper does not contain more than a brief mention of one thus relieved. In a footnote it is stated that still another case has been similarly operated on. He offers the following questions as of interest in connection with the subject:

1. Which is the better of the two surgical treatments of pruritus vulvæ, exsection of the affected skin or resection of the sensory nerve supply?
2. What is the best surgical technic for isolating and resecting the sensory nerves supplying the vulva?
3. What has been the permanent result of this operative procedure in the experience of those who have performed it or have had the opportunity of watching cases afterward?
4. If a cure of the pruritus can be expected, is there a likelihood, or has any one clinical evidence to present, of the development of kraurosis vulvæ, and possibly of an associated epithelioma?

19. Congenital Dislocation of the Hip.—The first portion of this article only is included in this issue. The authors tabulate their cases and report certain of them briefly. All thus far reported have been progressing well. They remark on the slight dependence placed by Lorenz in these cases on the x-rays, and state that their experience has confirmed the impossibility of relying much on them. One of the most difficult of all the cases was by the radiograph, apparently the most favorable.

22. Infection from Puncture of the Finger or Toe.—Manley calls attention to the large number of cases of serious phlegmonous inflammation occurring from slight punctures of the fingers or toes. These occur far more frequently in the winter and spring seasons and at the time when carbuncle, felon and erysipelas are most common. The difference from erysipelas in these cases is simply the absence of redness and metastatic invasion. Lymphangitis is always well pronounced, but the real mischief only begins when the vascular supply is compromised. Vasomotor paralysis is always an early phenomenon. Whatever the termination the pathologic feature is slow to yield. He warns against the use of narcotics in these cases and insists on the importance of local treatment. Nothing less than the free use of the scalpel will suffice. The limb must be freely exsanguinated in the areas of greatest distention. The tissues must be disinfected. Here he insists on the importance of the use of the Powell-Phelps mode of directly charging the tissues with pure carbolic acid, followed by neutralization with strong alcohol. After a surgical procedure opium is useful as well as other stimulants. When the temperature falls small doses of calomel, quinin and bitter tonics may be given. Recovery is likely to be slow, more or less functional embarrassment and stiffness remain for some time and in some cases have been permanent.

23. The Urethral Sound.—The following general rules for the use of the steel sound are given by Dowd:

1. When the urethra has been involved by inflammation, specific, or otherwise, no instrument, and especially the steel sound, should be used until the urine is clear excepting for shreds or floating particles. (Prostatic plugs.)
2. The urethra should in all cases be flushed with an antiseptic solution (formaldehyd, 1/3000) before the passage of any instrument. Following its withdrawal an astringent should be used, preferably silver nitrate 1/10000.
3. A sound should never be passed for at least three months following acute gonorrheal infection, and then only when the urine is as in No. 1.
4. When dilation of a stricture will answer, sounds are increased in size according to the tissue forming the pathologic growth and its location. True gonorrheal strictures of the deep urethra may be dilated five or six numbers at each sitting, up to 18 or 20 F.; following this, two or three numbers should be the rule.
5. In case of traumatic or gonorrheal stricture in the pendulous urethra, or when the sound is followed by marked irritation, etc., cutting gives the best result.
6. When the contraction seems not to dilate without too much force, weekly treatments being followed by considerable irritation, making the interval 10 to 14 days is generally followed by the most gratifying results.
7. Stricture can be permanently eradicated. This occurs when, after dilating the circular muscles of the canal to their fullest extent, without rupturing, no bloody string is found in the washings after four to six dilations which have varied from one to four months apart.

31 Fatal Case of Poisoning by Chlorate of Potassium. A. R. Ellis.

25. Uremia.—The peculiarities of uremia and its treatment are noticed at some length by Thomson, who remarks that there must be a variety of distinct toxemias included under this condition as commonly understood. He thinks there is one special poison which is quite common and which is generated in the kidney, and acts very much like the secretion of the suprarenal gland, producing high blood tension. For special cases he believes aconite is a vasodilator par excellence. He would recommend its systematic use as long as the pulse remains both tense and frequent, so as to lessen the strain on the heart, check the progress of vascular disease and increase defective urea excretion. In cases, however, where chronic endo-arteritis has co-existed with obliterated arteries, we can not safely utilize this drug. We should hesitate to employ it in old people, though it sometimes may be used where the pulse is quiet and there is exacerbation of chronic renal trouble. In puerperal eclampsia he says we have a remarkable illustration of such a poison being rapidly formed and giving rise to extreme high tension, but here complicated with rapid and powerful heart action. In this case the speediest and best vasodilator would be venesection, but if that be objected to, then veratrum viride should be given in large doses according to the effect on the tension of the pulse. Aconite is too slow in such cases. He does not incline much to the thyroid theory of this condition under such circumstances. In cases of organic disease of the kidney he remarks that the subject is extensive and he can only notice a few features. In scarlatinal nephritis the best prophylactic, in his opinion, not only against nephritis, but against its running a bad course, is to begin at once with a laxative dose of calomel, repeating it every night until the tongue desquamates. We are to look to the condition of the kidneys and almost universally the first danger signal is not albuminuria, but diminution in the quantity of urine and a fall in its specific gravity. When nephritis has developed and is advancing we should use the rectal douche with normal saline solution at 115 F., allowing at least two gallons of hot saline to run in and out at a time, the best instrument for this being Kemp's rectal irrigator. Certain special points in chronic interstitial nephritis are mentioned. Many people go along without indications of renal disease until uremic convulsions or other symptoms announce its existence. He believes in the great majority of such cases a new element, septic invasion of the kidneys by bacteria, especially by the colon bacillus; has entered into the case. He also remarks that he specially dreads cholera morbus in elderly persons, and should always investigate the kidneys in such cases. The prognosis in any case of chronic interstitial nephritis must always be uncertain because we can never tell how much good kidney there may be left. The diet is a matter of some importance and he would exclude any full meat diet. He remarks particularly on the difference in proteid metabolism between the day and night hours. The patients are apt to be worse in the morning, and in cases with melancholia, migraine or Graves' disease with this particular symptom he shuts off red meats. We should bear in mind these particulars when we aim to regulate a man's life who has a high tension pulse and rigid arteries. The chemistry of these night generated poisons is yet to be worked out, but he thinks they have much to do with the changes in the alimentary canal, connected with the nitrogenous elements of food, and every person with cirrhosed kidneys should be enjoined, like an asthmatic, not to eat heartily after midday. One of the best remedies for auto-infection and a prophylactic against the dangers of chronic interstitial nephritis, is life in the open air. A mild climate in winter is needed by such a patient as much as by a bronchitic or phthisical patient. Intestinal antiseptics, especially minute doses of bichlorid of mercury or sodium iodid for prolonged periods, are advised. In conclusion, he points out the differences between interstitial and parenchymatous nephritis and the different problems of treatment in the two cases. He hopes that Edebohl's surgical method will have good results. Last of all, he remarks in regard to albuminuria, that it is only a symptom, the significance of which greatly varies.

26. **Constipation.**—Hirschman's article is a description of the Houston valves with the operation for their treatment. He thinks these valves are the cause of a very large proportion of the cases of constipation, and it should be the duty of every one who has to treat any condition of the rectum to thoroughly examine and find whether these valves are hypertrophied or interfering with the normal function.

27. **The Gall Bladder.**—The question as to the value of the gall bladder to the organism is remarked on by Hutchinson. He looks at it from the point of view of its comparative anatomy and its mechanical action and the variations we find in its condition. He remarks, to sum up, that:

> The gall bladder is a nearly functionless organ, inadequate in size to act as a reservoir of any value for the bile, inadequate in muscular power, and in mechanical position, to exercise any important effect on the pressure of the bile flow, entirely absent in many species without interfering with the processes of digestion or the vital functions in any way, capable of removal from a species in which it is normally present without noticeable injury, and chiefly notable as a settling basin for the formation of gallstones, a suitable harbor for the multiplication of pathogenic bacteria, or for the assumption of pathogenic properties by nonpathogenic forms. In short, it seems a source of danger at least double any possible usefulness which it may possess.

41. **Nitrous Oxid and Ether Anesthesia.**—White advocates the preliminary use of nitrous oxid where general anesthesia is required. It is the safest anesthetic, diminishes the vomiting, hastens reaction and diminishes shock. The apparatus is bulky, which is a disadvantage, and the original cost is an item which has to be taken into account. He recommends, however, the method for more general use for the reasons given. While he does not believe it will supersede chloroform, it will be instrumental in reducing the deaths during anesthesia with which we are altogether too familiar.

42. **Foreign Bodies in the Ear.**—Goodbred calls attention to the constitutional symptoms following the introduction of foreign bodies into the ear and varying very much in different cases. In one case which he reports typhoid fever was diagnosed, but on removal of a pea which had been inserted high up in the nostril the condition was completely relieved. Another case almost like this was followed by like relief after removal of the foreign body. He does not say why the presence of a foreign body in the ear or nose should cause erysipelas in one patient, catarrh in another, fever resembling typhoid in another and in others no symptoms at all, but he calls the attention of the profession to these facts.

51 *The Treatment of Obesity. A. E. Taussig.
52 A Report of a Case of Unusual Recurrent Somnambulism. Wm. Shirmer Barker.
53 History of a Case of Bladder Exstrophy. T. C. Witherspoon.

51. **Obesity.**—Taussig sums up the treatment of obesity in reducing the income below the outgo. It is a matter of indifference, he says, whether the proteids, carbohydrates or fats are restricted, but the diet must be carefully selected and the number of calories estimated. From easily accessible tables, the normal weight of the individual corresponding to height, sex and race can be ascertained and the diet restricted accordingly. The restriction of water as well as a fat, rich diet represent merely technical aids and are sometimes of service and often not. Hydrotherapeutic procedures, especially with properly regulated exercise, increase considerably the combustion of body fat. Only in exceptional cases would he use thyroid preparations, and then in small doses where a rigid diet is poorly borne or where weak circulation or other conditions prevent a sufficient increase in exercise. Alcohol should be entirely excluded from the dietary of the obese. It is con-

sumed in the tissues instead of fat, which is thereby left over to accumulate in the body.

57 Pyothorax. O. T. Maynard.
58 A Case of Pemphigus Neonatorum Associated with a General Infection by the Staphylococcus Pyogenes. J. C. Miller.

54. **Pregnancy Following Nephrectomy.**—Pregnancy after nephrectomy has been very rarely observed. Baldwin was able to find but two cases besides the one he reports himself. It would naturally be supposed, as the author remarks, that when the work of two kidneys is being performed by one a patient would suffer more from the effects of pregnancy than ordinarily. He reports two cases of his own observation, in both of which there was a successful outcome and apparently good health following, though in one case the patient died of typhoid within a year. These two cases, together with the three in Bovée's report, while not numerous enough for generalization, would seem to indicate that the prognosis of pregnancy after nephrectomy is by no means unfavorable.

55. **Typhoid Fever.**—Moorehouse has studied the mortality statistics of typhoid in Cleveland for the thirteen years from 1890 to 1903, and finds that it furnished 3 per cent. of the total deaths; 19 per cent. of all tuberculous deaths occur between the years of 20 and 25; 36 per cent. between 20 and 30, and 50 per cent. between 18.5 and 35.4 years. The proportion of deaths from typhoid fever in total mortality was 1.8 per cent. in males, which is rather in excess of the females, being 58.1 per cent. of the total typhoid mortality. In proportion to the total, the greatest number of deaths both for males and females is found in the five-year period between the age of 20 and 25 years. In this respect the mortality of typhoid fever differs essentially from that of tuberculosis, in which the highest mortality is past middle life. There is a notable decrease in the percentage of typhoid deaths in married individuals as compared with that in tuberculosis. The percentage excess of married over single mortalities in tuberculosis is four times that found in typhoid fever, from which Moorehouse concludes that tuberculosis frequently delays and prevents marriages. He finds presumably no relation between the conjugal condition and death from typhoid fever unless it be a moderate increase in liability to infection on the part of the unmarried, and this, if it exists, is thought to bear equally on the two sexes.

68. **The Vitality of Bacteria.**—Weaver has investigated the throats of scarlet fever patients with the idea of studying the vitality of the streptococcus. His conclusions are given as follows:

> 1. Streptococci are almost always, if not constantly, present in the throat in cases of scarlatina. In the early stages they are usually in very large numbers, becoming less numerous as the disease progresses. 2. The streptococci in the throat of scarlatina patients resist drying as long as the other bacteria usually present, and they often outlive all other forms, being alive as long as ninety days after the material is collected. 3. These streptococci remain alive for a long time in milk. 4. A small amount of sugar in nutrient media increases their value for the cultivation of streptococci. 5. Streptococci from scarlatinal anginas are not different from streptococci from other sources so far as cultural and morphologic peculiarities are concerned.

71. **Actinomycosis of the Central Nervous System.**—Howard reports a case and reviews the literature. He finds the condition rare, only 5 primary cases, including one here reported by the author, and 13 secondary cases have been published. It usually affects males in the prime of life; only two cases in females have been reported. Of the primary, 3 were reported as instances of streptothrix infection, and only one was regarded as a typical actinomycosis. Of the 13 secondary cases, 8 were regarded as typical actinomycoses, 2 as probable and 2 as cladothrix and 1 as streptothrix infection. All the primary cases with the exception of one were acute, while of the secondary the lesions were recent and usually the cause of death. In 2 each of primary and secondary cases the organisms were cultivated. No mention is made of any attempt to test the acid resisting powers. Actinomycotic granules were noticed in several and in one there were multiple nodular masses instead of abscesses, and in one other there was a firm mass the size of a hazelnut in the third ventricle and in the foramen of Monro. Primary lesions in secondary cases were usually in the lungs and bronchial glands. In one case the actinomycotic process extended directly through the skull to the meninges and brain. Howard remarks that in the present state of our knowledge all the processes caused by micro-organisms, having a mycelium of branching, interlacing and sometimes radiating threads are to be considered as actinomycosis, and that organisms with the above characteristics, whether or not they form "drusen" and clubbed hyphæ in the tissues, are to be regarded as actinomyces. A satisfactory classification is at present impossible, and it seems doubtful to him whether it is advisable to consider tuberculosis as an actinomycosis. There are two types of actinomyces, the acid-resisting, including the *Bacillus tuberculosis*, and the other, non-acid-resisting or acid-bleaching. Typical tuberculosis is always caused by the prominent member of the former, and typical actinomycosis by the prominent member of the latter group. It is better, he says, with Lehmann and Neumann, to use the term "actinomycetes" for the large number of organisms of the latter group, which were present in the case reported.

79 A Case of Self-induced Cystitis Due to the Colon Bacillus. I. Leopold and I. Valentine Levi.
80 *Inversion in the Treatment of Acute Pulmonary Edema in Young Children, with Report of a Case. Thomas S. Southworth.
81 Congenital Hypertrophic Stenosis of the Pylorus. H. Beardsley.

76. **Congenital Tumors of the Kidney.**—From a study of these tumors, and of their literature, etc., Strong concludes as to their embryonic origin. The term carcinoma can not be applied to them as the adenomatous type is evident, and as the epithelial elements do not take origin from the developed glands of the kidney. Histologic comparison shows that these

tumors resemble the embryonic Wolffian body. There is a continuous system of tubules and their derivative cell masses throughout the tumor. The cell masses are derived from the tubules by retrograde metamorphosis. Histologic characteristics vary with the age of the part; the pelvic region is oldest, showing complete differentiation of mesenchyme and mesothelium. The metastases are youngest and show an embryonic condition where all cells are alike. Bilateral tumors are coincident and not metastatic. Metastases may occur through the lymph stream as well as through the blood stream.

77. **Typhoid in Children.**—Koplik reviews the records and statistics of typhoid in children, remarking that in the new-born it runs an atypical course, the classic symptoms being absent. Its infrequency in children under 2 years of age can be readily explained on external grounds. During the first year and in most of the second year of life infants and young children are fed with food which has been subjected to heat to a greater or less extent. Such children, it must be assumed, become infected either through the food or from contact in some uncleanly way with infectious material. The mortality is probably larger than is generally appreciated. The mortality apparently diminishes after the second year of life, though Koplik thinks this is true only in mild epidemics. As regards perforation, he has himself met with two undoubted cases, one of which was operated on, in a series of 100 cases. The heart, though undoubtedly affected, did not present the severer forms of myocarditis or endocarditis. These complications seemed to be rarer than in the adult. The mortality, of course, varies according to the severity of the epidemic, but typhoid fever in the new-born is in most cases a fatal infection. Up to two years of age it is uncertain, and statistics are not entirely reliable. From 2 to 10 years the mortality varies according to the severity of the type, sometimes high and then again very low.

78. **Endocarditis in Children.**—The instances of endocarditis and its cause in young children are reviewed from the literature by Blum, who finds that there is a condition of endocarditis that may occur in fetal life. The pathologic changes in these cases include thickening, shortening and agglutination of the valves. It may also create a predisposition to subsequent attacks in children thus affected. Acquired endocarditis is of common occurrence after the fifth year, and frequently in later youth, from rheumatism, scarlet fever, etc. Malignant endocarditis is evidently rare in children. The endocardium, like the tissues, has less power of resistance than in adult life, and especially so if congenital defects exist, which furnish a point of lessened resistance. Children are the chief sufferers from exanthemata, anad endocarditis secondary to this group of diseases is practically limited in its inception to children. About puberty the endocardium may be affected owing to the great demands made on the heart, and, unfortunately, there is a considerable number of cases of congenital endocarditis of the severe grade which never attain adult life. In fact, these severer cases other than those implicating the pulmonic orifice rarely exceed the age of 12. The predisposition to occurrence *in rheumatism, etc., is greater in childhood than in adult life.* While malignant endocarditis is rare, when it does occur it is usually associated with rheumatism. The child completely escapes from the atheromatous ravages of advanced age, but the influence which depraved systemic conditions in the mother, such as alcoholism, metallic poisoning, etc., may exert on the endocardial structures of the fetus can only be conjectured. That bacterial endocarditis may occur in the embryo he sees no reason to deny.

80. **Inversion in Pulmonary Edema of Young Children.**—Southworth reports a case where this manipulation was quickly applied in a case of sudden pulmonary edema, and was followed immediately by marked relief. After subsequent use of stimulants the child made a rapid recovery. Since a number of cases which had occurred in the same institution and were treated in the same way as regards medication, had succumbed, Southworth is inclined to think that inversion was an active factor in producing the recovery and a life-saving measure. The child was inverted and firm, steady pressure made over the lungs, with stroking pressure over the bronchi toward the head, squeezing out a little frothy fluid.

85 *The Diagnosis of Influenza. Bertram W. Sippy.
86 Concerning the Bacteriology of Influenza. Eldridge Wynekoop.
87 The After-Treatment of Influenza. John S. Perekhan.

82. **Hydrophobia.**—Bevan reviews the symptoms of hydrophobia and calls attention to its present prevalence. Statistics show that hydrophobia, during the last eleven years, caused 91 deaths in Chicago. He is satisfied that this does not represent the actual mortality, as some cases are not recognized or not properly reported. He thinks it is a duty to call the attention of the authorities to the prevalence of hydrophobia in the city of Chicago, and that by proper dog laws radically enforced it would be possible to eradicate the disease.

83. **Prostatic Hypertrophy.**—Ochsner formulates the indications for operative treatment in prostatic hypertrophy as follows:

> 1. Perineal prostatectomy is indicated in all cases of obstruction due to hypertrophy which can not be relieved for any considerable period of time by hygienic measures and medical treatment. 2. This is especially true in old men past the period of virility because in these cases it is not necessary to preserve the seminal vesicles. 3. In younger patients more persistent efforts should be employed to obtain relief with non-operative treatment and in case of operation the seminal vesicles should be preserved. 4. In the presence of stone of the bladder complicating or resulting from the obstruction due to enlargement of the prostate gland, the latter should be removed and the stone extracted through the perineal wound. 5. The contraindications to the operation are (*a*) acute infection, (*b*) advanced nephritis with or without pyelitis, (*c*) other coexisting conditions of sufficient importance to make any major operation very unsafe. 6. If possible, thorough preparatory treatment should precede the operation. This should consist in hygienic measures, rest in bed, drinking distilled water, irrigation of the bladder and the administration of non-irritating remedies which have a tendency to render the urine sterile. 7. In case the obstruction is complete and catheterization impossible because of the obstruction or on account of the resulting hemorrhage, an immediate operation is indicated. 8. The operation should be performed before patients have advanced to this condition.

He gives a tabulated list of 22 operations with their results, including cases of suprapubic and perineal prostatectomies, castration and vasectomy. From each of these operations there were a number of cases of complete cure. Of the total number 11 were cured, 7 improved and 4 died. All the patients but 2 were over 60.

85. **Diagnosis of Influenza.**—The different forms of influenzal attacks are described by Sippy, and in conclusion he says that a positive diagnosis is only possible by determining the influenza bacillus in various secretions. Aside from the bacteriologic proof, the presence of an epidemic of the disease offers important points in diagnosis, though it is probable that sporadic influenzal infection is not rare. Certain local and general manifestations of the disease have a minor value in the diagnosis, and their importance should not be underrated, as they may lead us to suspect what can be confirmed by bacteriologic proof.

88 *The Geographical Distribution of Insanity in the United States. William A. White.
89 *The Changes Found in the Central Nervous System in a Case of Rabies with Acute Mental Disturbance. Charles L. Allen.
90 Psychomotor Hallucination and Double Personality in a Case of Paranoia. William Pickett.

88. **Geographical Distribution of Insanity.**—White finds that insanity is far more prevalent along the eastern coast of the United States and also on the Pacific coast than it is in most other parts, though certain of the central states, like Ohio, Illinois and Missouri, show a large percentage. The cause of this he attributes to the increase in population and the stress of modern civilized life. No hypothesis founded solely on meteorologic or topographical conditions can explain the distribution.

89. **Rabies.**—Allen reports a case with postmortem. He finds that the lesions agree in general with those previously described, but while strongly suggestive in a case with suspicious history, taken alone without the animal inoculation they would hardly justify a positive diagnosis. From a study of the

literature of the subject and this case he concludes that neither the ganglionic changes of Van Gehuchten and Nélis, nor the rabic tubercle of Babes are absolutely characteristic of human rabies, though their presence in a suspicious case may be of considerable diagnostic value. The diagnostic importance of these changes in the dog is not yet settled, but their presence is suggestive and should always be sought for.

95 Giant Cell Sarcoma of Bone. Joseph C. Bloodgood.
96 Angioneurotic Erythema and Its Surgical Treatment by Neurectomy. Joseph C. Bloodgood.

91. Absorption of Granular Materials from the Peritoneum.—From a careful study of the conditions, which he reports in full with illustrations, MacCallum concludes that we find no support whatever for the belief that there exists a connection between the peritoneum and lymphatics, nor can we uphold the idea that the peritoneal cavity forms a part of the lymphatic system. Each of these cavities is lined with cells which retain their specificity throughout and nowhere merge into one another or into the adjacent connective tissue cells. Each develops independently, and it is only later that they come into such intimate relationship that the transfer of materials from one to the other is relatively easy. The idea of the complete specificity of the endothelial cells of the lymphatics was expressed also in a previous paper by the author, and has since been confirmed—indeed, one might say proven—by the embryological investigations of Dr. Sabin. And it does not interfere with the truth of these statements, that we find that the individual cells in any of these membranes are separable by adequate forces and that the mechanical violence of the respiratory movements is sufficient to force fine granules between them.

92. Diastolic Murmurs Without Aortic or Pulmonary Lesions.—The summary and conclusions of Cabot and Locke's study are given as follows:

> Diastolic murmurs without organic valve lesions are not uncommon in connection with dilatation of the aorta, localized or diffused. One of the cases reported seems to be of this type. 2. When the pleura and pericardium are adherent owing to tuberculosis or other causes, diastolic murmurs are occasionally audible in the precordia. Such murmurs are notably affected by respiration and by position; they are probably due, in most cases, to suction or pulsion exerted by the heart on portions of lung adherent to the pericardium (cardio-respiratory murmurs). 3. In cases of intense anemia, when the red cells are reduced to or below 1,000,000 per cu. mm., one occasionally hears diastolic murmurs not to be *explained* by permanent dilatation of the aortic ring nor as "cardio-respiratory murmurs," and not due to a diastolic accentuation of a venous hum. The cause of these murmurs is obscure.

94. Cardiac Traumatism.—The part played by traumatism in the production of pericarditis, endocarditis and myocarditis is the subject of Pleasants' rather long article. He reports a case of his own of traumatic pericarditis with autopsy, and reviews other cases from the literature. Traumatic endocarditis is also considered, and a case reported following contusion of the chest without fracture, but with an immediate onset of cardiac symptoms with fever. The development of chronic mitral insufficiency and chronic traumatic endocarditis occurring at varying intervals after traumatism is apparently more frequent. A tabulated statement is given and a number of cases reported of both forms developing into valvular disease. Traumatic myocarditis is represented by four cases taken from the literature, and, as the condition seems rare, a synopsis of reported cases is given. The author concludes that it can hardly be doubted that myocarditis occasionally develops as the result of contusions of the chest Other effects of trauma on the heart include the alleged dislocation in a case of Stokes, which he thinks was hardly a correct diagnosis. Aneurism and cardiac neuroses are also mentioned.

97. Nerve Anastomosis in Facial Paralysis.—Cushing reports and illustrates a case of nerve anastomosis of the facial to the spinal accessory similar to those reported by Ballance and Stewart, abstracted in THE JOURNAL of May 23, ¶76, p. 1474. The paralysis of the facial muscles is much less noticeable in the condition of rest since the operation, but extensive voluntary motion is only produced with simultaneous movement of the shoulders. Some independent control of special muscle groups in minor movements was regained also. Cushing remarks that the course of these impulses after an anastomosis similar to that described can only be conjectured, and it seems that there are two possible hypotheses:

> 1. That the cortical centers concerned in shoulder movements (trapezius) and rotation of the head (sterno-cleido-mastoid) may themselves in the course of time be educated by training to co-ordinate the impulses, which have been sidetracked into the motor area of the facial nerve, so as ultimately to lead to expressional movement.
>
> 2. That the cortical centers originally presiding over movements of the face continue to play a part in the co-ordinate action of these muscles, possibly influencing the higher neurones of the *N. acccssorius* through the intermediation of connecting tracts in the cortex.

98. Practically the same article appeared in THE JOURNAL of March 28, title 69, p. 874.

100. See abstract in THE JOURNAL, xxxix, p. 1409.

102. Ruptured Crucial Ligaments.—It would appear, as Robson remarks, that a force sufficient to rupture the crucial ligaments of the knee would lead to complete disorganization of the joint, but the case here reported demonstrates not only that the crucial ligaments may be ruptured without serious damage to the joint as a whole, but that their repair by operation is both feasible and hopeful as to ultimate result.

103. Anastomosis of the Popliteal Artery.—The case reported by Ferguson is of interest as being the only one so far as we know of in the literature. Anastomosis was made by the invagination method. The upper end was introduced into the lower for a distance of a quarter of an inch and held there by four retention sutures of fine silk. The free edge of the lower end was sewed around the upper with a fine continuous suture of the same material. Then the temporary gauze ligatures which had been put on were removed and the blood allowed to enter the limb. Pulsation at the ankle was restored at once and the result was in every way favorable. The patient had some difficuty in straightening his limb after operation, owing to the cicatricial contraction which was removed, occasion being taken to examine the artery at the time. Pulsation was present both above and below the seat of the anastomosis.

105. Hepatic Syphilis.—Cumston reports several cases of hepatic syphilis operated on with good results. He disagrees with some authorities who object to operative interference in these cases. He remarks that the essential thing is that the tumor be situated not too deep in the hepatic substance so as to necessitate extensive destruction of the organism and risk the patient's life. Where the gumma is covered only by a thin layer of parenchyma resection is without danger and relatively easy.

108. See abstract in THE JOURNAL of January 10, p. 118.

American Practitioner and News, Louisville, Ky.

February 15.

112 Sarcoma, with Report of a Case. A. David Willmoth.

the conditions minutely and concludes that there is no inherent reason for the difference between the mortality of the two armies. It is due, among other things, to the more careful selection of recruits. The examiners are not allowed to pass on a larger number than 150 in one day. The family antecedents of the recruits are investigated and the recruit known to have a hereditary burden is submitted to minute and prolonged observation before final acceptance. He concludes with the remark that the population is beginning to feel the beneficial effects of the three great social laws (insurance against sickness, against old age and against industrial accidents) which cost the German empire at the rate of $250,000 a day. Compulsory military service has been organized in Germany since 1814, while it is of comparatively recent date in France, 1870. For all these reasons the general standard of health and hygiene in the army is at a high level in Germany, but there is no intrinsic reason why other countries can not reach the same by appropriate hygienic and prophylactic measures.

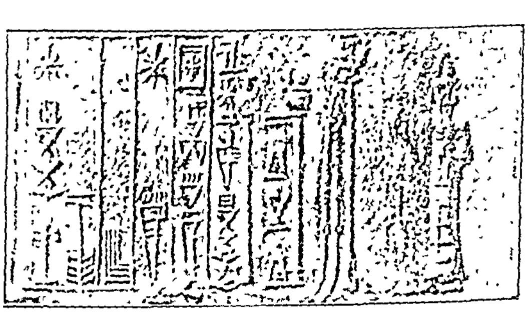
69. **Warning Against Paraffin Prothesis in Gynecology.**—Kofmann comments on the enthusiasm with which he introduced this method of correcting deformities into Russia and his constant success until he enlarged its sphere to include gynecologic affections. His first case of the latter was a middle-aged woman who had suffered for years from granular endometritis and mild prolapse. She was treated by abrasio mucosæ, and two weeks later, for the prolapse of the vagina, by injection of paraffin according to Gersuny's directions. After two syringefuls of 10 gm. each had been injected the patient suddenly began to cough and succumbed in twenty-four hours to embolism of the lungs. This use of paraffin Kofmann believes is not adapted to gynecology. It should never be employed in a very vascular region. Since this occurrence he has followed Eckstein's directions, using paraffin with a melting point not less than 57 to 60 C., and in a syringe protected against cooling. The tips must be short and kept warm. He adds that Gersuny's suggestion to insert the tip first and aspirate must not be forgotten, as a trace of blood shows that some vessel has been invaded.

70. **Separate Phases of Commencing Narcosis.**—Hofmann states that the benumbing effect of the first whiffs of ether is not the prerogative of ether alone but is observed likewise with chloroform and mixed narcosis. In every narcosis there is evidently a preliminary phase in which the sensation of pain is deadened while consciousness is still retained. It occurs in every case, but is more or less transient. Sudeck calls it the "Ether Rausch," and he and others have been able to perform even protracted operations with it, repeatedly bringing the patient into this stage without allowing him to pass beyond it into actual narcosis. Hofmann suggests the term "early narcosis" for it to distinguish it from the later, profound narcosis. The two are separated by the period of agitation. The phase of early narcosis may be prolonged by further administration of the anesthetic into what Kronacher calls "half narcosis," or into the profound stage. The "Ether Rausch" is, therefore, not an innovation, but merely the effort to utilize the phase which every anesthetist produces with the first whiffs of any anesthetic. Hofmann himself prefers for this early narcosis the ether drop method with or without previous administration of morphin. With a few c.c. of ether he can banish the sensation of pain in one or two minutes. The patients feel and hear everything, but suffer no pain.

74. **Legal Status of Surgeon in Abraham's Time.**—Oefele is a student of the cuneiform language of ancient Babylonia, and regrets that so little attempt has been made by the legal and medical professions to delve in the cuneiform records stored in such profusion in the British museum and elsewhere. Almost all that is known about them is what the theologians have published, but the code of 282 laws promulgated by King Hammurabi, a contemporary of Abraham, was the basis of all international and national laws then and for thousands of years thereafter, as the Roman code is accepted to-day. A copy of the entire code was found in the excavations at Susa. The laws of Moses were evidently based on it, but Moses ignored medicine and surgery in his compilation, while eleven of the paragraphs in the Hammurabi code referred to them. The standing of the surgeon before the law more than four thousand years ago is thus presented to us. The seal of the surgeon Urlugaledin has been preserved, and depicts the god Adar and next to the god the surgeon's instrument, a peculiar whip for scarifying and vessels for cupping. The word for this instrument may be translated "copper or bronze scorpion awls" and the seal shows the copper instruments tied to the end of the two whip lashes. It must have required considerable skill to manipulate the instrument properly. This copper instrument was also used to remove cataract. About 1,500



years later the cuneiform word used for the surgeon was "master of the lancet," but his instrument was described then as resembling more a pointed finger nail, and thus differs from the "scorpion awl." The code also throws light on the social position of the surgeon as it stipulates that the architect of a building or builder of a ship receives a fee for his services, but the surgeon is paid like the tailor, carpenter or potter for his work. The code establishes the remuneration for removing a cataract with the "scorpion awl" as 10 sekels when the subject is a freeman, 5 if a freedman and 2 for a slave. A sekel was about 25 cents. If the subject dies after the surgeon has applied the "scorpion awl" or the eye is lost after he has removed a cataract, if a free man, the surgeon's hands shall be cut off; if a slave, the surgeon must replace slave for slave. If the slave's eye is lost the surgeon shall pay half the price of the slave, and if a cow or ass dies after he has treated it with the "scorpion awl" he shall pay one-fourth its value. Oefele remarks that these extreme penalties may possibly be due to the fact that the ancient Babylonians believed that good and bad fortune depended on the stars, and that the surgeon, by operating on lucky days, could ensure success. The calendar expressly stated that the seventh and its multiples were unlucky days. The failure of an operation was, therefore, due either to the surgeon's lack of skill or to his neglect of the astrologic influences.

75. **Filling for Cavities in Bones.**—Mosetig-Moorhof has plugged the cavity left in the bone after removal of a lesion into sound tissue in 120 cases, and the filling was never expelled while the foreign substance was always perfectly tolerated. Every case healed without a fistula. Two patients with necrosis of the thigh bone were able to leave the hospital with a perfectly healed wound in three weeks. Radioscopy has shown that the filling is gradually substituted by neoformation of the bone exactly filling the cavity without leaving a trace of it by the end of a year, as he shows by radiograms of an instructive case. The filling is, therefore, merely temporary. It supports Nature in her horror vacui and serves as a stopgap until the bone can form again. He has found it very important to apply the filling with as careful asepsis and drying out the cavity as a dentist uses in filling a tooth. He then pours into the cavity a semisolid mixture of 60 parts iodoform in 40 parts each of spermaceti and sesame oil. The ingredients are heated together to 80 C. for fifteen minutes and then allowed to cool while the vessel is being constantly shaken in order to spread the iodoform evenly through the mass. When wanted to use it must be rewarmed to about 60 C. and well shaken. It is then slowly poured into the cavity until it is filled to the brim. After waiting a few minutes for it to harden, the flap of soft parts is sutured in place, leaving the fistula opening for drainage or a strip of rubber tissue. There is no bleeding nor secretion from a cavity thus filled. The method is applicable for cavities left from chronic osteomyelitis, necrosis, abscesses or cysts in the bones and carious foci. It is also a valuable aid in carious processes in a joint, and especially in fungous lesions in the joints. He thinks that the latter should be treated surgically at once on account of the danger of general infection from the focus. Any disturbance from resection of the bone can be obviated with this iodoform filling. He makes a practice of treating these lesions in children by removing the cartilage of the joint with the thinnest possible slice of bone, and extirpates most thoroughly the entire capsule and the fungous degenerated neighboring tissues in the soft parts. He is careful also to chisel out all isolated foci, leaving a cone-shaped cavity and filling the defect with the iodoform mixture. The results have been excellent. Growth proceeds undisturbed as the epiphysis cartilage is nowhere injured. Resections in the ankle, wrist and hip joints can be followed by applying this filling to the cavity left, although it is not properly a cavity in a bone. In case of extensive defect in the soft parts it is possible sometimes that part of the free surface of the filling is cast off. But even in this event the substitution of bone for the filling in the depths proceeds undisturbed.

76. **Operative Treatment of Paralysis of Peroneus.**—Deutschlaender's method is distinguished by the facts that the paralyzed tendons are transplanted into muscles innervated by the intact tibialis, and the transplantation is done on both sides of the foot. The necessity for symmetrical treatment has not been sufficiently regarded hitherto, he thinks. The tendons are crossed over the malleolus before being transplanted, which affords a firm support for them and also gives the tibialis a stronger hold for supination and the extensor for pronation. Another advantage is that the fibers of the tendons run obliquely to the axis of traction and are thus less liable to stretch. The stumps of the tibialis anticus muscle are sutured to the tendons at the point where they cross, which promotes dorsal flexion. It is even possible that active flexion may be regained as even much paralyzed muscles are liable to have their function restored when placed under sufficient tension. The various steps of the simple operation are illustrated.

77. **Fixation of Wandering Kidney.**—Ruggi first slits the fibrous capsule after exposing the kidney through a lumbar-costal incision. The capsule is then detached, and each half is seized with forceps and twisted with three or four turns of the forceps. Catgut is then tied around the base of the twist on each side, and the ends of the thread are drawn out through an intercostal space and tied, after the kidney has been drawn up into its normal position by traction on these threads. He has found by tests on the cadaver that these twists will bear a strain of 800 to 1,200 gm. By this technic the kidney is brought under the shelter of the ribs while its anatomic structure is not interfered with in the least.

78. **Buried Metal Plates for Abdominal Wounds and Hernias.**—Witzel and Goepel recommended in 1900 to use silver wire netting to close abdominal wounds. In 1890 Trendelenburg reported a case in which he had inserted a disc of bone for the purpose. The same year Isnardi commenced using thin metal plates and has now an experience of 50 cases of hernia thus treated, including some children. His technic differs from that of all the others as he places the plates directly on the peritoneum. Adhesions soon form and the plate becomes soldered to the peritoneum and moves with it. In a case of umbilical hernia and in one of hernia after appendicectomy, pregnancy and delivery followed without disturbances of any kind or discomfort from the buried plate. He uses a very thin round or oval perforated plate of flexible metal with a rounded, raised, smooth edge. It is wider than the hernial opening, and is inserted sideways as a button is worked into a button hole. The peritoneum is flattened by the plate and does not grow like a funnel into the relics of the hernial opening. It also prevents pressure on the cicatrix from the intestines. It is tolerated by the tissues without appreciable reaction and does not hook into them. He always concludes by suturing with wire, which practice he has been following for five years, using wire for all buried sutures and ligatures of vessels, and for laparotomies, etc. At the autopsy of a child who had been operated on with the plate for a large inguinal hernia and died from measles two years later, the plate was found solidly fastened to the peritoneum.

81. Improved Technic for Subcutaneous Injection of Quinin.—Aufrecht has long advocated quinin in the treatment of croupous pneumonia and puerperal infection. It is not a specific, but it seems to counteract the injurious action of the bacterial products in the blood and have a generally favorable influence on the course of the affection. The mortality from croupous pneumonia had ranged from 13 to 24.9 per cent. until this quinin treatment was instituted, and since then it has never been over 10, and one year as low as 5 per cent. in a total of 382 cases. The improvement in the technic which he now recommends, as already mentioned in THE JOURNAL, p. 1394, is the addition of urethane, a mild sedative, which renders the quinin much more soluble. Without it the hydrochlorate requires 34 times its volume of water, but with .25 gm. urethane to .5 gm. quinin hydrochlorate water to make only 5 gm. is all that is needed. This mixture keeps for weeks if not exposed to severe cold, and in any event redissolves on heating. He injects it in the side of the abdomen, repeating it once or twice in twenty-four hours for eight days. His experience indicates that the unpleasant by-effects of quinin are less intense than when it is given by the mouth.

91. Prophylaxis of Cancer.—Mohr urges that more attention should be paid to the precursors of carcinoma, and the transitional phenomena.

93. Tests of Borax, Etc., on Frogs.—The experimental research described shows that salt and vinegar were much more harmful for the skin of the living frog than borax or boric acid.

94. Irrigation of Biliary Passages for Diagnostic and Therapeutic Purposes.—Kuhn's experience with 59 patients enables him to cordially recommend the practice of thorough rinsing of the biliary passages into the intestine during and after operation. The flow of water sweeps out hidden calculi and by distending the walls, massages the entire route. A fluid can be used that has a dissolving tendency, Carlsbad water or eunatrol, for instance, and a direct therapeutic effect thus be induced. He believes that recovery is prompter and more complete when the gall bladder is not removed.

99. Harmlessness of Boric Acid.—Liebreich contributes several arguments in favor of the harmlessness of boric acid.

103. Intravenous Medication.—Mendel attributes to Landerer and his cinnamic acid treatment of tuberculosis, 1888, the revival of the intravenous method of medication. Mendel has himself had excellent results from intravenous administration of arsenic in form of sodium cacodylate or the preparation of arsenic known as atoxyl. The general nutrition and metabolism were improved and the effects were particularly striking in tuberculosis, anemia and in chlorotic girls. He reports actually brilliant results from it in 3 cases of exophthalmic goiter. By the end of six to eight weeks the exophthalmus, struma and palpitations had diminished to such an extent that the patients considered themselves cured. In 9 cases of tuberculosis, 3 in the early stages were cured and the others very much improved. The tuberculous process was arrested, or at least materially retarded. In a case of disfiguring chloasma of the forehead, the increased circulation in the skin under the influence of the arsenic, resulted in the rapid absorption of the pigmentation. He has found it also extremely effective in the disturbances due to the natural or artificial menopause. He treated 10 cases of tuberculosis by a combination of intravenous injection of 1/10 mg. of tuberculin and arsenic in the form of atoxyl. The general reaction to tuberculin by this route seemed to be less severe, but the local reaction was more intense. He claims that the benefits derived commend it unhesitatingly for further trials. He found the intravenous technic free from danger or pain, and reports that 20 cases of syphilis were rapidly cured by intravenous injections of the form of mercury known as sublamin, which is peculiarly mild in its by-effects, never causing stomatitis nor other troubles in his experience, while the therapeutic effect was rapid and energetic.

104. Electric Light Treatment of Upper-Air Passages.—Freudenthal reviews his favorable experience with electric light in treatment of laryngeal tuberculosis, hay fever, etc.

111. Boric Acid in Obesity Cures.—Lenz noticed unpleasant symptoms in some cases but none in others, and recommends tentative use of this means of reducing obesity on account of its convenience and efficacy in certain cases. He begins with small doses and increases to 1.5 to 2 gm. of boric acid a day, dissolved in hot water, in three portions during the day. One of his 6 patients gained 9 pounds in eleven weeks, with no restrictions as to diet.

118. **Experimental Study of the Functions of the Hypophysis.**—Pirrone removed the hypophysis in 6 dogs, partially resected it in others, and also studied the effects of electric stimulation in another set of animals, while in still others he studied the influence on the function of the hypophysis of severe traumatisms affecting the nervous system. He found that total ablation was invariably fatal after a stage of motor disturbances, great depression, rapid emaciation and cachexia. Other phenomena observed after ablation of the organ were due to the traumatism of the operation and should not be attributed to the loss of the hypophysis. The composition of the urine was not modified by total ablation, but the pulse was accelerated at first and later became slower than usual. Electric stimulation slows the pulse and accelerates the respiration, the reaction increasing in intensity as the stimulation is applied farther to the rear.

123. **Cardiotoxic Serum.**—Ferrannini asserts that Belfanti and Carbone were the first to call attention to the fact that an animal (horse) treated by intraperitoneal injection of rabbit blood furnished a serum extremely toxic for rabbits. From this simple beginning has grown the famous researches of Büchner, Ehrlich and others in regard to the prepared serums active against the cells from which they were originally derived. Ferrannini has been experimenting with a cardiotoxic serum produced by injecting guinea-pigs with an emulsion of frogs' hearts and rabbits with toads'. The serum thus obtained was injected into frogs and toads. In small doses it had a stimulating action while in larger ones it invariably caused at first an exaggeration of the heart action followed by a gradual depression to complete suspension. Normal serum had no such effect.

126. **Epileptic Paroxysmal Tachycardia.**—Bellisari has collected 7 cases and has himself observed 4 which demonstrate the existence of a variety of paroxysmal tachycardia that should be regarded as an epileptic equivalent. The same as the latter, the etiology may include neuropathic heredity, trauma or cortical foci. The symptoms do not differ from those of essential tachycardia and the diagnosis must be based on the history of the case, the nocturnal onset, the premonitory and consecutive symptoms and the influence of bromid medication. These attacks of tachycardia may be interpreted as conditions of arrest of the cardio-inhibiting function of the vagus from some irritation of the cortex. The prognosis need not be so guarded as is necessary in other forms of unknown cause, although repetition of the attacks may entail permanent hyposystolia possibly complicated by some anatomic lesion independent of the neurosis. His first case was a man of 34, unmarried, free from venereal and alcoholic antecedents. At 16 he had commenced to have epileptic seizures which had gradually become attenuated and ceased entirely for two or three years, when he began to be affected with nocturnal attacks of tachycardia and tachypnea, becoming more frequent until they occurred nearly every night and several times in the night. The cardiac seizures increased in intensity as the ordinary epileptic seizures became attenuated, until finally the tachycardia was accompanied by coughing, vomiting and profuse diarrhea on each recurrence. The pulse was small, soft and 130 in the morning after such an attack, the respiration 52. There was no edema, no enlargement of the liver. Digitalis was administered, but without the slightest effect; the attacks recurred with increasing intensity. After three days it was substituted by potassium bromid and sodium iodid and the patient commenced to improve at once. The bromid rapidly conquered both the tachycardia and the tachypnea rebellious to digitalis. The patient was able to resume his occupation for five years, occasionally resorting to the bromid when threatened with return of the cardiac attacks, but symptoms then developed, indicating uncompensated hypertrophy and dilatation of the heart, with moderate but continuous tachycardia. The bromid was ineffectual at this stage, and the patient soon succumbed. The second patient was a woman of 33, an epileptic from infancy, with indications of spastic infantile hemiplegia. The menstrual period was accompanied by intense asthma for two or three days, during which time the lung increased in size by an entire rib, and tachycardia for a few hours was noted. During the time when these disturbances were observed the otherwise frequent epileptic seizures were suspended. The seizures evidently had a double equivalent in the asthma and the tachycardia which in turn seemed to be connected in some way with the menstrual molimen. The third patient was a woman of 46, not an epileptic but with neuropathic heredity, intelligent, with a history of enuresis nocturna and night terrors. Sixteen years before she was first seen she was awakened one night by extreme tachypnea and tachycardia for an hour, followed by intense headache. Similar attacks recurred every four or five months and were accompanied by profuse sweating or urination. The oldest of her seven children is an epileptic and feeble minded. Glycerophosphates and bromids were prescribed and the patient has had no recurrence of the attacks during the year since. The fourth patient was a young man who exhibited hemiparesis and transient aphasia in consequence of cerebral embolism occurring in the course of acute articular rheumatism with peri- and endo-carditis and mitral insufficiency. As these symptoms improved the character became altered and a typical epileptic seizure occurred, followed by others every week or two, lasting from ten to thirty minutes. As the convulsions came on the pulse rose to 150-160, and this tachycardia continued for about an hour after the seizure. Under the bromid treatment the seizures were arrested and nothing was left but the tachycardia, preceded by the aura, and these in turn finally grew less and less. The parallel evolution of the tachycardia aand epileptic seizure demonstrated that both were evidently due to the same subcortical lesion that had produced the hemiparesis and aphasia. The existence of the organic lesion of the heart in this case can not be invoked to explain the attacks of tachycardia, given their constant coincidence with the seizures and the persistence of the aura after the seizures had been arrested, precursor of the tachycardia and the testimony to its nature.

136 (No. 7.) Injuries of Eyes During Birth. Sidler-Huguenin.—Beitrag zur Kenntnis der Geburtsverletzungen des Auges. (Commenced in No. 6.) Seven cases.

131. **Treatment of Fractured Patella.**—The principles of Bärlocher's method are suture of the parts around the patella, never of the bone itself; suture of the capsule; dry treatment of the exposed joint, and complete closure of the wound, with active movements commenced early. In 28 cases thus treated 20 healed without disturbance. In 5 cases there were some complications elsewhere, and in 3 there were complications at the knee, phlebitis in one case with resulting ankylosis. In another the knee was injured during delirium tremens, and the third exhibited symptoms of pneumonia the day after the operation with fatty degeneration of the heart, and soon succumbed. Only 5 of the total number still use a cane. The patients remained in the hospital from 35 to 68 days, with 2 exceptions, and were able to use the knee freely when dismissed. Examined a year or more afterward there was apparently complete restitution in nearly all.

135. **Dangers of Perpendicular Mountain Trips.**—Zangger remarks that many persons grow old without being aware of it and can live their usual life in perfect health. Let some sudden strain come on their vascular system and the deterioration of age becomes abruptly evident, with apoplexy or heart

failure as the possible result. He warns that such a strain is entailed by the railroads to the tops of mountains, and emphasizes their dangers for persons over 55, even for those apparently in robust health. He relates that when the railroad on the Jungfrau was planned the promoter was required to show that such an ascent was harmless before the scheme received official sanction. He accomplished this by having 7 persons carried by 42 bearers from Zermatt up the Breithorn to a height of 4,171 meters, a difference in altitude of 2,130 meters. The medical examiners testified that the results showed that healthy men could be carried to this height without objective injury to their health, but so soon as they attempted any active movements, disagreeable and even alarming symptoms of circulatory disturbances were liable to manifest themselves. The subjects of the tests were all more or less used to the mountains. Zangger does not think it necessary to forbid mountain trips to all persons over 60, but recommends that they should test their capacity by doing some mountain climbing at the lower altitude before venturing on the ascent. They should stop over two or three days at intermediate points, and should never attempt to go above 3,000 meters. He gives directions for treatment of the disturbances that may arise and describes an instructive case in detail in which acute dilatation of the heart was the unmistakable result of a trip up the mountains. In ten hours the individual in question went from 840 to 2,590 and 1,410 meters, and again a few days later in a few hours from 1,390 to 840 meters. The heart symptoms grew constantly worse for twelve days until the picture of collapse was presented, with Cheyne-Stokes respiration and symptoms resembling those of the heart failure after diphtheria. About .02 morphin was injected, and after sleeping twenty-four hours he awoke refreshed and gradually recuperated during the following month, but the dilatation of the heart still persisted to a certain extent. The harm done by these abrupt changes of altitude may not become manifest for several days after the subject has returned home. The connection between apoplexy or heart failure occurring under these circumstances and the previous mountain trip has been hitherto overlooked.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Public Service.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended May 14, 1903:

Assistant Surgeon-General H. D. Geddings, to proceed to Elkins, W. Va., for special temporary duty.

Surgeon D. A. Carmichael, granted leave of absence for seventeen days from May 19.

Surgeon P. C. Kalloch, to assume temporary command of the service at Portland, Me., during absence, on leave, of Surgeon S. D. Brooks.

Surgeon S. D. Brooks, granted leave of absence for three days from May 19.

P. A. Surgeon J. H. Oakley, granted leave of absence for three days.

P. A. Surgeon S. B. Grubbs, granted leave of absence for one month. To rejoin station at Gulf quarantine at expiration of leave of absence.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence, on account of sickness, for fourteen days from April 10.

Asst.-Surgeon T. F. Richardson, granted leave of absence for three days from May 8, under provisions of paragraph 191 of the regulations. To proceed to Gulf quarantine station for special temporary duty.

Asst.-Surgeon M. W. Glover, to proceed to Newbern, N. C., for special temporary duty.

A. A. Surgeon B. F. Duke, granted leave of absence for four days from May 18.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for five days.

A. A. Surgeon G. A. Gregory, granted leave of absence for four days from May 18.

A. A. Surgeon K. S. Kennard, granted leave of absence for twenty-one days from April 25.

A. A. Surgeon J. W. Stevenson, granted leave of absence for seven days from May 11, under provisions of paragraph 191 of the regulations.

Pharmacist A. M. Roehrig, granted leave of absence for five days from May 12, under provisions of paragraph 191 of the regulations.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending May 16, 1903:

P. A. Surgeon R. K. Smith, resignation accepted, to take effect May 19, 1903.

A. A. Surgeon J. R. Dykes, U. S. N., appointed assistant surgeon April 18, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 16, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, April 25-May 2, 2 cases; San Francisco, April 26-May 3, six cases.

Colorado: Denver, April 11-25, 53 cases.

District of Columbia: Washington, May 3-9, 1 case.

Florida: Jacksonville, May 3-9, 3 cases.

Georgia: Atlanta, April 29-May 6, 1 case.

Illinois: Belleville, May 3-9, 5 cases; Chicago, May 3-9, 14 cases, 4 deaths; Galesburg, May 3-9, 4 cases.

Indiana: Indianapolis, May 3-9, 7 cases.

Iowa: Des Moines, May 3-9, 4 cases.

Kansas: Wichita, April 26-May 9, 1 case.

Louisiana: New Orleans, May 3-9, 18 cases.

Maine: Biddeford, May 3-9, 1 case.

Maryland: Baltimore, May 3-9, 4 cases.

Massachusetts: Holyoke, May 3-9, 1 case.

Michigan: Detroit, May 3-9, 12 cases; Flint, May 3-9, 1 case; Grand Rapids, May 3-9, 4 cases; Port Huron, May 4-11, 1 case.

New Hampshire: Manchester, May 3-9, 2 cases; Nashua, May 3-9, 3 cases.

New York: Buffalo, May 3-9, 3 cases; Rochester, April 30-May 7, 1 case, 1 death.

Pennsylvania: Johnstown, May 3-9, 3 cases; McKeesport, May 3-9, 1 death; Philadelphia, May 3-9, 26 cases, 2 deaths.

South Carolina: Georgetown, May 18, 1 patient from Charleston.

Tennessee: Memphis, May 3-9, 2 cases imported.

Utah: Salt Lake City, May 3-9, 3 cases.

Wisconsin: Milwaukee, May 3-9, 2 cases.

SMALLPOX—FOREIGN.

Belgium: Brussels, April 18-25, 7 deaths; Ghent, March 28-April 25, 6 deaths.

Brazil: Rio de Janeiro, April 5-12, 3 deaths.

Canary Islands: Las Palmas, April 4-18, 44 cases.

Colombia: Bocas del Toro, April 21-28, present.

Great Britain: Birmingham, April 18-25, 7 cases; Dublin, April 18-25, 8 cases, 1 death; Liverpool, April 25, 69 cases, 6 deaths; London, April 18-25, 9 cases; Newcastle-on-Tyne, April 18-25, 2 cases; South Shields, April 18-25, 2 cases; Sunderland, April 18-25, 7 cases.

India: Bombay, April 7-14, 67 deaths; Calcutta, March 28-April 18, 7 deaths; Madras, March 28-April 3, 1 case.

Italy: Palermo, April 18-25, 1 case.

Mexico: City of Mexico, April 12-26, 21 cases, 11 deaths.

Russia: Moscow, April 4-11, 5 cases, 4 deaths; Odesa, April 11-18, 4 cases; Warsaw, April 4-11, 8 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, April 5-12, 29 deaths.

Colombia: Panama, April 30-May 7, 3 cases, 1 death.

Costa Rica: Limon, April 23-30, 2 cases.

Ecuador: Guayaquil, April 11-18, 2 deaths.

Mexico: Tampico, May 2-9, 2 cases, 2 deaths.

CHOLERA.

India: Calcutta, March 28-April 11, 206 deaths.

PLAGUE.

Australia: Perth, to March 23, 16 cases, 8 deaths; Rockhampton, to March 28, 2 cases; Townsville, to March 28, 3 cases.

Brazil: Rio de Janeiro, April 5-12, 2 deaths.

India: Bombay, April 7-14, 1,360 deaths; Calcutta, March 28-April 11, 1,779 deaths; Karachi, March 29-April 5, 195 cases, 161 deaths.

Address.

DEVELOPMENT AND CARE OF CHILDREN.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON DISEASES OF CHILDREN AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS, MAY 5-8, 1903.

JOHN C. COOK, M.D.
CHICAGO.

It is with no little temerity that I enter on my duties of opening this Section of the Fifty-fourth Annual Session of the American Medical Association, while it is a great pleasure to appear in this capacity in my native heath, as it were, for my childhood and early boyhood days were spent in the sunny south, and I feel that my early impression enables me to appreciate the high-grade sensitiveness of the southern gentleman, and when, added to this, he is one of our own cloth, I feel that I can bespeak for myself and my brethren the cordial welcome always accorded a visitor in the southern fold.

To this glorious old city that has been the scene of so many disquietudes we have come to study with you the best methods of the most important subject now before not only the medical profession but before the whole world, namely, how best to save the lives of the tender babes and develop them into sturdy manhood and womanhood, and let it be the privilege of this Section to consign to oblivion the dogmas and superstitions surrounding the treatment of diseases of children, and by our scientific accomplishments reflect the rays of the noonday sun on true preventive medicine.

It is also within the province and power of this Section of the great medical body to refute the most dangerous and far-reaching condemnation of the medical profession that has ever been made, namely, that physicians are a national detriment because they preserve the weak and thereby weaken the whole nation. But we are at the wheel and helm not only to preserve the weak but to strengthen them, and so prove ourselves, as in the past, the greatest body of human benefactors that ever has or ever will exist.

Let us see anatomically and physiologically what this specimen is we call a child. Is it true that a man is simply a grown-up child or a child an immature man? Once clear on this subject, we are better prepared to study its requirements and judge of its capabilities. Fehling gives the percentage of water in a very young fetus as 97.5. Instead of this being a permanent feature, it is merely a transitory one and diminishes steadily until after birth it is 74.7 per cent. The decrease continues gradually but more slowly until in the adult it is only 58.5 per cent. Oppenheim's researches show us that the osseous system undergoes marked changes, that the organic and inorganic elements bear inverse ratio to the age from one to twenty-five, and this fact gives us an insight into the relative period over which ossification is spread.

Thus the walls of the shafts continue to grow thicker from birth to puberty and in some instances do not attain full development before the twenty-fifth year. Take, for instance, the bones of the head and face, the upper and lower jaw begin to ossify in early life and continue to change all through childhood and youth and do not attain full development until after puberty. Again, taking as an example the layers of cartilage which act as cushions between those important parts of the skull, the basi-occipital and basi-sphenoidal bones do not allow them to unite until after the twentieth year. This condition serves to make other changes that are equally if not more important. We should keep these things in mind for their bearing on the rightful exercise of a child's functions.

The muscular system develops simultaneously with the osseous, but neither of them make a harmonious and uninterrupted development. A child is more supple than an adult, not because he has more muscle but a relatively larger proportion of muscle to tendon. As a matter of fact, there is less of the elements that make the body weight, and the percentage of water is greater and the myosin less.

A few facts of relative proportion will serve to illustrate the anatomic and physiologic difference between childhood and adult life.

The circulatory and respiratory system, the changes in the heart are noteworthy. In the fetal stage it occupies nearly the entire thoracic cavity. At birth it is still relatively larger than in the adult life. Mathematically, the new-born heart is 0.89 per cent. of the body weight, while the adult heart is only 0.52 per cent.

The rapid and irregular strides made by the lungs at different periods of development make the compensation between the lungs and heart a little uncertain during the developing period. Also the relative difference between the heart and the arterial system at different periods of growth makes an uncertain and unreliable blood pressure through youth and adolescence.

The blood elements themselves are different in childhood from adult life, rich in the so-called young-form elements, while the over-ripe is only one-half as abundant as in maturity.

The changes in the nervous system from birth to maturity afford us many examples of the difference between the child and adult. At birth the central nervous system, as well as the peripheral, is almost entirely unmedullated. Hence, we find the fibers of the spinal cord, the medulla, corpus quadrigeminous and the pons varolii mainly somatic. The motor nerves receive their attachments much earlier than the inhibitory centers are developed, hence the many objectless movements that characterize the unmeasured exercise of the young.

Thus maturity is gradual and full growth is only reached between puberty and adult life. It is our duty to guard and conserve every atom of energy through this period of unfolding and budding life, realizing that they are bundles of possibilities unsolidified, which begin at the beginning and end we know not where.

The study of biology teaches us that the higher the organism the slower the development, hence the necessity for a long period of protection and care. Take with this the many periods of stress and functional demands on the nervous system and we can realize the greater necessity for a wise and careful guardianship.

And who shall give this care and protection to the child who has been unfortunate in the selection of its parents? How much have we a right to expect from the state and how much is the state at liberty to interfere?

As citizens we have a right to expect common protection to our lives and property in return for a consideration the state exacts of us, but the state has a higher and more exalted motive in surrounding us with every care and protection, for we are its soul and body, its producer and consumer, its parent and offspring and, as every child born is a possible parent and citizen, it behooves the state to give it every protection and opportunity for a full development of all its best and highest capabilities, with a minimum facility for the development of the depraved side of humanity.

There is a wonderful significance in the fact that humanity continues its life on the earth by means of successive generations, and to conserve the nation's integrity one must protect and conserve the rising generation, and were it different how meager our advancement would be. It is only step by step of succeeding generations that the greatest heights of science, art and humanity are attained.

REGULATIONS OF CHILD LABOR.

Let us see what is being done by the state for the betterment of our successors. In speaking of the state, I refer to it in its specific rather than its general meaning, as the government of the United States has concerned itself little, if any, in the rising generation, while the states that have taken any action at all have regarded the subject from such different points of view one would think they were dealing with entirely different nations, with different environments and with entirely different objects to be attained.

Arkansas, Kansas, Georgia, Idaho, Oregon, North and South Carolina, New Mexico, Texas and Florida have not grappled with the subject at all, while about half as many states have only covered one phase of the subject.

The state of Washington does not allow small children to work in mines or females to act as public messengers. Utah protects children from working in mines only. Arizona protects her children against public exhibitions. New Hampshire has no law on child labor, but a very efficient compulsory education law. Alabama and Virginia have child labor laws pending. Fortunately in some of these states there are few manufacturing establishments.

Many of the other states have very efficient laws, others voluminous ones. Some states have legislated well on the labor question with little or no attention to compulsory education or provision for a child's time who is not allowed to work.

As early as 1874, in the Ten Hour Act, Massachusetts began to throw a safeguard around her children. In 1876 an act was passed making ten years the youngest age a child could be put to work in a factory. In 1883 the limit was raised to twelve years during school time, and in 1885 a law was passed prohibiting children working under twelve any time of the year. In 1888 the age limit was again raised to thirteen years.

These figures show the necessary changes from actual experience and have some bearing on the whole subject of the age at which children should be allowed to become wage earners. And yet, notwithstanding the fact that many of the states have enacted excellent laws on the subject of child labor, the application of them falls far short of the purpose for which they were intended. In many instances they only legalize the subject, protect the state and vicious parent, act as a sedative to public conscience and pervert their own purpose.

In all states having labor laws they take the age of the child as the standard of capability and the affidavit of the parents takes prestige over everything else in establishing this fact, which in many instances not only works physical detriment to the child but establishes in its innocent but honest mind its parents as liars; and, as the manufacturer is not required to be any better than the law, the applicant is accepted without investigation. With him it is business, not philanthropy. It requires but a slight stretch of the imagination to see this child at the juvenile court. One million seven hundred and fifty children under 15 years of age are wage earners in the United States at the present time, and this number has increased 100 per cent. in the last ten years.

Just one hundred years ago Sir Robert Peel directed the people of England's attention to the disastrous effect of child labor on the nation. He, with others, was startled to find they could no longer replenish the army from the manufacturing districts, the early factory labor had so dwarfed the rising generation.

Notwithstanding the vigor with which he and others attacked this plague, it took the best part of the following half century to consign it to oblivion. Germany, France, Austria and Russia soon followed England's example, and now "Free America" owns and controls the market in child slavery.

The result of this can not be different in this country from what it has been in others—a physically, mentally and morally weak and depraved generation, and I believe it eminently proper that a sentiment against this wholesale slaughter of childhood should emanate from a representative body of men such as this, who are devoting their lives to the care and improvement of the rising generation, and who are better prepared and more willing to cope with the subject than are any other body of citizens.

And what can we do? Elevate public sentiment and guide sentimental legislation. The state can better afford to support and educate a child from 7 to 20 years of age than it can to support paupers and *discipline* criminals from 20 to 50.

Not that I would deny any one the privilege of honest toil—far be it from me—for work is a civilizer, a developer of character and dignity, and endows the human race with an independence that nothing else will replace, and it is stated by men of keen observation and broad experience that no man in this country has ever risen to eminence, either in the medical or legal profession, who has not worked with his hands. It is not labor that makes or mars our characters, but the kind and environments during the developing period that prepares us for our future and greater tasks of life.

Factories aggregating a great number under unhygienic surroundings tend to minimize, while individual labor under good sanitary conditions tends to magnify the individual unit.

If any development occurs after a child is put to running a machine in a large factory, it is a one-sided one, making a genius or a freak, as circumstances may determine, depending on the part over-stimulated at the expense of many or all of the other faculties. Thus it is children come to have weak bodies and minds, not so much from heredity as from environment.

One may see how true this is (I quote from Oppenheim's "Development of Child") by the following report of the committee of the British Medical Association of 1883 in regard to the relative stature of boys between 11 and 22 in the population at large and at the industrial and reformatory schools. They found the tallest boys in proportion to their age in the public school. Below them came the boys in the so-called middle-class schools, and then those in the elementary schools and in the private military schools, and last of all the inmates of the industrial school, a difference of six inches existing between the first and last class.

This proportion is true at any period between the two mentioned ages. What has been found to be true of stature is also true of weight, a difference as great as twenty-five pounds existing between the first and last class; and what is true of body measure and weight is a strong indication of the mental state. Dwarfed bodies, as a rule, mean dwarfed minds and souls.

Thus, to break in on the nutrition and disturb the rhythm of development for one day means the marring of the body and harmony of a perfectly finished product. To conserve every atom of nutrition and force, protect every budding function, that we may deliver to posterity a perfect being becomes our highest and greatest aim in life.

How may we aid the state in adjusting this important matter? There are conditions which are familiar to all of us that should and must take prestige over all established state laws. As, for instance, the necessity of a child working to support its own life, to aid in the support of a helpless mother, or add to the maintenance of a young brother or sister, and I believe it is a conceded fact that there are no established rules or scales of weight, measurement, or mental development by which all children's ability to become wage earners can be established, as there are children that fulfill the requirements of the best established laws, yet by inheritance or previous environments they are physically and mentally unable to perform the duties required of the average child.

This is verified by a letter from Dr. James H. Dowie of New Holland, Georgia, who has had twenty years' experience with child labor in cotton mill life. Says the Doctor: "The children who are physically able for the duties do not succumb nearly so quick, if at all, to the factory labor. The wizen, wan and dejected ones so frequently seen in cotton mill towns are the results of over-taxation of the immature and lack of judicious application of efficient laws."

As it is not within the power of the medical profession to immediately change the present condition, we may improve it by lending our aid to the sanitary surroundings of the factories in which children are employed, see that at least 250 cubic feet of air space be allowed for each person employed from sunrise to sunset and that 400 cubic feet be allowed each person employed between the time the sun sets and rises, and that sufficient ventilation be arranged so that the entire air be changed every hour, with sufficient pure water to drink and an ample supply of sunshine, toilet facilities for both sexes employed, and to have such laws enacted as will provide for the protection, development and education of all children, with efficient administration and application of the law.

I would, therefore, recommend that each state have appointed a commission consisting of five members, at least two of whom shall be physicians, to have jurisdiction over all education and labor questions, and that said commission be appointed by the supreme judges of its state, and they in turn nominate or appoint inspectors, so that the question of child labor shall be forever removed from petty politics and vicious contract labor.

THE DIAGNOSIS OF CUTANEOUS SYPHILIS.*

ISADORE DYER, Ph.B., M.D.

Professor on Diseases of the Skin and Secretary New Orleans Polyclinic; Lecturer and Clinical Instructor on Diseases of the Skin, Medical Department Tulane University; Dermatologist to Charity Hospital, New Orleans; Editor New Orleans Medical and Surgical Journal, Etc.

NEW ORLEANS.

INTRODUCTION: ANACHRONISMS IN COMMON METHOD OF DIVIDING SYPHILIS INTO ARBITRARY GROUPS OF PRIMARY, SECONDARY AND TERTIARY.

The differential diagnosis of skin affections has always seemed a veritable *pons asinorum* to the practitioner, to whom all lesions look much alike and to whom the gross picture always seems present.

In the types of syphilis, however, exact lines of distinction characterize every set of lesions, and the experienced recognize these at once, often without even discussing the reasons why, the picture fixing the diagnosis on its own lines.

In current texts, now and latterly, so much of the traditional anachronisms have prevailed that it has seemed to the writer that some one, somewhere and somehow, should call a halt and at least utter a word against the further teaching of a dogma, which most of us feel is wrong and which as many of us would like to get away from.

With students of skin diseases in the undergraduate classes there is always most difficulty in fixing types; in syphilis this becomes additionally difficult when the very rules of diagnosis are as often excepted as found; so much so that the student is taught the opinion that syphilis is a "protean" disease, as if it were ever ready to change its type while you looked at it, when, as a matter of actual fact, no disease of the skin is as true to its types as syphilis nor more exact in its lack of confusion.

The "copper color" related as a part of the macular eruption of syphilis is a veritable mare's nest—the writer has never seen it—yet this type is a point so fixed in the minds of the writers of texts and in the field of vision of the student that on examination he always describes the roseola of syphilis as "copper colored." The induration of the chancre, the exact division of syphilis into a series of eruptions in fixed sequence, arranged according to a schedule of days, weeks, months and years, an easy rule of three, all these are beyond the experience of men who see syphilis, and these things should not be taught, for they are false teaching, and every day the men who do teach these things make excuses to themselves for doing so. Syphilis is certainly characterized more for its variants in types than for its obedience to rule. Our sole idea here is to throw the gauntlet to provoke a sort of discussion which will make more clear the definition of the types of cutaneous syphilis, according to some line of thought which is within the experience and observation, and not simply arbitrary, dogmatic, traditional or speculative.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, W. L. Baum and J. A. Fordyce.

In teaching cutaneous syphilis, for several years the writer has made the rule to look on its definition as determined by the lesions which presented, irrespective of antecedent history, irrespective of time or of the patient's record.

DEFINITION.

We have considered syphilis as a contagious and infectious disease due to a specific *causa morbi,* at present unknown, producing, among other constitutional and local symptoms, certain definite manifestations on the surface of the body, in the skin and deeper tissues.

DIAGNOSIS OF CUTANEOUS EVIDENCES.

Chancre.—The first evidence of syphilis is the chancre, which may show any time after infection, periods of time related being from four or five days to as many as 100 more days.

Location.—Irregular. At point of inoculation. On the genitals usually, but may be at any point exposed to venereal or accidental infection. Usual points of distribution are the penis, vulva, vagina, urethra, scrotum, thighs, pubis, lips, fauces, tongue; unusual, nose, fingers, neck, eyelids, cheeks, eyebrow (arch), etc.

Arrangement.—The chancre is usually a single lesion, but there is no reason why two points of inoculation at the same time might not each present a chancre after due incubation; we may note a double chancre of the upper eyelid, a chancre on each forefinger in a medical student as coming under the writer's observation.

Description of the Lesions: *Types.*—The chancre has various types. While described as a classic, the type made the rule, the Hunterian chancre, is the exception, and, as a matter of fact, is found oftener in its full classic form in the extragenital, accidental locations than in the common venereal location.

(*a*) *Hunterian Chancre.* 1. *Shape.*—A rounded ulcer, more or less deep, with central cavity and elevated borders.

2. *Consistency.*—Base and borders are indurated, the induration resembling cartilage in its consistency and hardness. The surface of the ulcer is more or less smooth, with thin discharge, depending on the cleanliness and general condition of the patient.

3. *Size.*—The size varies up to a silver half dollar (the larger lesions are more apt to be extragenital). This lesion is classic when found on the lips, tongue or at points where the thicker skin allows the cellular infiltration and induration.

Variant Types.—Much more usual is the excoriated lesion, found usually on the genitals, smooth, superficial and shiny, bleeding easily; slight border, thin parchment-like base, rolling between the fingers. This last point, however, we wish to say is not pathognomonic of the chancre, though the texts claim so; it may occur in any lesion of long standing on the genitals, mucous membranes of the foreskin and vulva particularly.

More usual still is the excoriated lesion, with irregular base, some cellular involvement, raw and tending to break down in parts.

Both of these types are small, seldom larger than a silver dime and neither sufficiently distinct as chancres to be diagnosed in all cases.

DIFFERENTIAL DIAGNOSIS.

Epithelioma.—Gradual development, deep central ulceration, little cellular inflammation outside of lesion, tendency to crust over a discharge which is thick and dirty. Microscope. On the genitals the epithelioma is almost always verrucose or nodose.

Lupus.—Presence of tubercles which ulcerate from time to time. Microscope.

Traumatic Ulcer.—History of injury, limitation of ulcer, lack of induration. On the genitals, however, there enter for diagnosis such conditions as herpes, chancroid, epithelioma and traumatism (hair cut, abrasion, etc.).

We must remember that the fear of syphilis in most patients brings them to the consultation and that the history is most times to be discounted by that fact. Again, as Taylor has often said, you can get any kind of a history from a patient if you go about it in the right way and if you ask him questions enough.

Herpes.—With the vesicles presenting the diagnosis is simple, but the patient may have been inoculated with syphilis when the herpes was produced, that is, if it followed the sexual act.

Postherpetic Ulcer.—This presents the same clinical picture as the excoriated chancre, and it can not be differentiated from it. It has the raw surface, indurated, parchment-like base, heals slowly, is slightly painful and only differs in one particular, *quid est,* the chancre is usually single, the herpetic ulcer more often presents in two or three points along the line of nerve distribution. I have seen postherpetic ulcers last for two months.

Chancroid.—The chancroid is differentiated on the points of development after starting, multiple lesions, beginning in a pustule, often seen as it is breaking, destruction of tissue, limitation of location to genital area; but when mixed with a chancre the diagnosis of the latter is practically impossible.

Traumatism.—The hair cut, abrasion, excoriation from friction, after a few days, or enough time to determine an ulcer, may not be distinguished from a simple excoriated chancre, which each then resembles. As a matter of actual fact, these are often the sites of the chancre, either inoculated at the time of the traumatism or in subsequent exposure.

THE IRREGULARITY OF SEQUENCE IN ERUPTIONS OF SYPHILIS.

The fact that any time from a few weeks to several months or years may elapse before general cutaneous evidences of syphilis appear, and that in many instances these never show, would tend to make the usual division of the skin sequences fallacious. Logically the term secondary should apply to lesions prior to those tertiary and logically these should not be concomitant.

Yet many cases have no secondary lesions, still they present tertiary lesions; others have both at the same time; still others have the so-called secondary lesions years after tertiary lesions have shown.

SYPHILIS IS A SELF-LIMITED DISEASE.

Depending on the resistance of the individual this means the restriction of the evidences of syphilis to simple types or the surrender of the individual to greater or less degree of malignancy.

These are to be determined by the powers of elimination of the individual, evidenced by the appearance of simple inflammatory lesions, macules, papules or by the failure to eliminate, evidenced by the lesions which are deposited in the skin and deeper tissues, at times in other organs as well, such lesions as tubercles and tumors (gummata). Not infrequently the lesion is a pustule, breaking down as it is eliminated, but with a limited area of destructive process.

If we classify the general lesions of syphilis, then, into groups of inflammation and of deposit we can study each of these according to its own type and each presents its points of distinction.

Examples only are needed to present the principles of diagnosis, as this paper is meant only to plead for a method free of the confusion which awaits the average physician, not the expert, and incidentally to evidence the desire to create a general opinion that syphilis is not so difficult of diagnosis in its cutaneous manifestations.

THE IDENTITY OF EACH LESION ON ITS OWN MERITS AND ITS DIFFERENTIAL DIAGNOSIS FROM OTHER LESIONS OF SIMILAR CHARACTERISTICS.

With this end in view, we shall take examples of the inflammation group of lesions of syphilis and present each with points of diagnosis; the deposit lesions to follow, and all this independent of any arbitrary relationship to the primary, secondary or tertiary distinctions.

LESIONS OF INFLAMMATORY GROUP IN SYPHILIS.

The macule of syphilis presents the following characteristics:

Size.—Usually small, as large as little finger nail, not necessarily uniform in size.

Form.—Irregular in outline, not rounded, a splotch on the skin.

Consistency.—Level with the skin, fading on pressure, but leaving slight discoloration behind. As the lesion disappears this discoloration sometimes stays for a time.

Color.—The lesion as it first shows is rose color, pink or yellow red, raw ham color. As it fades on pressure or in the natural course of the disease it leaves a yellowish color, "dirty-lace" color, often described as "copper colored," which color is only seen in the mulatto or light negro skin.

Arrangement.—Single lesion always discrete, not confluent. No grouping, really showing as an exanthem or rash.

Distribution and Location.—Found on flexor surfaces of thighs, belly, forearms, arms, back and chest (slightly usually), forehead, sides of scalp.

Differential Diagnosis.—The absence of subjective symptoms, the subacute character of the redness, the appearance gradually over a number of days exclude measles, scarlet fever, etc.

The absence of scales, the fixed size of lesions, which does not increase, once formed, exclude pityriasis rosea, tinea versicolor and seborrheic dermatitis.

The presence of the pediculi pubis and the blue, ashy gray color of the lesions over the belly and sides of chest exclude the maculæ ceruleæ of pediculosis pubis.

The Papular Lesions.—The papular lesion of syphilis is more highly organized than the macular and presents several types:

The flat papular syphilide, the circinate and lenticular papular syphilide have a common location and distribution on the flexor surfaces especially, the chest, arms and forearms, the forehead as the usual sites.

The circinate lesion is less numerous than the other two, more discrete and is not uniform in size.

In color each of these presents the raw-ham color. Except from seborrheic dermatitis the differentiation is clear. In this disease the scales are numerous, in syphilis unusual, in both the scales are greasy, but in the syphilide the base is less apt to be affected—it is usually firm—borders elevated in the circinate form, while in seborrheic dermatitis the base of the lesion under the scales is apt to be moist or even raw.

The acuminate, or rounded papular syphilide, is discrete, widely disseminated, very general and especially on the extensor surfaces of the arms, legs, shoulders, and is found on the face, in the "frame" of the face and on the forehead.

Smallpox clusters its papules, prurigo itches constantly and psoriasis spreads its lesions peripherally.

The miliary syphilide is unique in its type, having a clustered grouping on the extensor surfaces in numerous patches of lesions of uniform size, deep seated, small (miliary) and with a dull color, often not much different from the normal skin. These lesions occasionally vesiculate and would need to be differentiated from herpes zoster, if they were not so numerous, in many patches and bilateral and symmetrical.

Condyloma.—The condylomatous papular syphilide is characterized by the location on or near the mucous membranes or tender surfaces, as over the scrotum, thigh, the foreskin, vulvæ, anal folds and between the fingers and toes. Rarely the condylomata are seen on the neck or on the face, flat, excrescent, warty at times, but marked by a more or less smooth surface, constantly wet with a discharge.

On the tongue and in the buccal cavities the condyloma is flatter and marked by a white film.

The diagnosis from ordinary warts (acuminate) and from ringworm lesions, common in some of these locations, is easy. The flabby, soft consistency, together with the sticky discharge, makes the diagnosis.

In the mouth the soreness, rawness and crescentic contour are unmistakable.

The papillary syphilide is found in little elevations, like seeds of fine grain, in the palms, on the fingers and on the soles and toes. It may be picked out, leaving a slight depression, which disappears gradually with the scaling skin. The diagnosis is clear with the few lesions, bilateral and rather uniform in size.

LESIONS OF DEPOSIT.

A word only regarding the lesions of deposit. When syphilis has passed the period in its infective process where most of the element of toxicity is removed, there remain here and there certain traces of the virus, uneliminated, left in the tissues, either permanently encapsulated or ready to slough away on the slightest provocation.

Among the tissues or organs which may be involved is the skin. Here the syphilitic deposit has certain types, always readily recognizable.

The Tubercular Syphilide.—The tubercular syphilide as a single lesion may occur generally, in more or less close distribution, on the extensor surface, bilaterally. More often the tubercle occurs grouped in masses of lesions, found in particular sites of selection: the forehead, scalp, nose, scapular region, back, hands (palms especially), thighs, knee joint, just above or below, etc.

These lesions are either small as a pea, firm and rounded in the skin, staying for months, years even, as a fading and growing mass of tubercles, "bunched" together, without ulcerating or else only here and there breaking down.

The other type of the tubercular lesion of syphilis is serpiginous, ulcerating and scarring with pigmentation in the process. The horse-shoe, kidney-shaped, crescentiform clusters of lesions are typical of this lesion.

Perhaps no lesion of syphilis goes more undiagnosed than this one. The only diseases having any resemblance at all are tuberculosis cutis and leprosy. Lupus vulgaris differs in the color of the lesions, their consistency and the arrangement irregularly in groups of rapidly breaking lesions. Moreover, the tubercles of lupus are usually found in the face, seldom elsewhere. With leprosy the tubercles are always disseminated, single, little tendency to cluster, the arrangement being usually determined by the gradual evolution of the tubercle, which may develop from a pinhead-sized lesion to a lesion as large as a marble, hence lesions of all sizes are found between these two. The color, moreover, is *sui generis,* a dusky brown red.

The Gummatous Syphilide.—The gumma of syphilis is more properly not strictly cutaneous, but has its own diagnostic points. It is usually limited, but may be general. Sites of predilection in the order named: leg, forehead, scalp, nose, shoulders, buttocks. The distribution is usually at points of weaker circulation: On the leg, along the line of the tibia or in the middle third, etc. The arrangement is by single lesions, varying in size largely according to its distribution. The lesion itself may be superficial, crusted, with slight cellular inflammation about it; it may be nodular, gradual in evolution, finally sloughing as a whole, or it may be large, flat and only slightly elevated, here and there forming punched-out, small ulcers, afterwards causing the whole gummatous mass to slough, leaving the ulcer of syphilis with its single odor and characteristic configuration.

Sarcoma, mycosis fungoides, etc., are to be differentiated. Clinically the points of diagnosis are based on the fact that sarcoma begins in a nodular mass, growing in size and that it breaks down by excoriating and gradual ulceration. Mycosis fungoides begins with a granuloma, growing warty and increasing in size until it is many times larger than the initial lesion.

SOME CONCLUSIONS.

The above outline has been done as cursorily as possible and is not intended as an exhaustive diagnosis of syphiloderms.

If each type of syphilis, then, may carry its own points of recognition and definition, capable of diagnosis on these points, why not use such a method of diagnosis which precludes the speculative line of thought which only clouds or forbids an intelligent conception of syphilis?

DISCUSSION.

Dr. Henry G. Anthony, Chicago—The author states that he has never seen a copper color in the syphilitic roseola. The copper color does not occur in every case of roseola, but it may be observed in some cases. In these cases the eruption is first of a rosy color and within a few days becomes copper colored. That fact has been greatly exaggerated and is now exaggerated by the general practitioner, but to the dermatologist it is no longer a point of importance.

The Doctor mentioned that form of infection in which chancres will appear on different parts of the body at the same time. That is what the French call chancre à distance. I have observed a case in which the patient had at one time a chancre of the tongue, a chancre of the penis and a chancre of the finger. In connection with chancre à distance there are two points to which I wish to direct your attention: First, the literature of these cases shows that the chancre virus is always deposited in these different locations at one and the same time. The patient does not get a chancre of the tongue and ten days later have the virus deposited on the finger, and then ten days later still on the penis, but it is deposited at one and the same time in all the different locations. The next point in chancre à distance is that unless there is mixed infection the gland is enlarged only in connection with one of the chancres and not with the others.

I wish to direct attention to the differential diagnosis between a chancre and a gumma. A gumma situated on the penis will many times produce a lesion which can not be distinguished from a chancre. Leloir makes this distinction; he says that a chancre is an abrasion which takes on induration, and a gumma on the penis is an induration which becomes eroded or ulcerated. Kaposi makes the statement that there are cases in which a diagnosis can not be made from an examination of the lesion and one can only make a diagnosis by considering the history of the case and considering lesions on other portions of the body. Several cases of that kind have passed under my observation. A patient gives a clear history of syphilis, has a perforation of the palate resulting from an ulcerated gumma occurring five years before. He presents himself with a lesion of the penis which at first you would diagnose as a chancre. Knowing the literature of chancre redux, chancriform syphilome of Leloir, or gumma of the penis (these terms are all synonymous), the first diagnosis which would come into your mind would be a gumma and not a second infection of syphilis. You would only make the diagnosis second infection of syphilis when driven from the diagnosis gumma by the subsequent symptoms, such as enlargement of glands at the proper time, the appearance of the roseola, neuralgic pains and temperature which mark the onset of secondary syphilis. Strange to say, no attempt has ever been made to differentiate these lesions by microscopic study of their structure.

Dr. A. H. Ohmann-Dumesnil, St. Louis—The subject is very interesting to me in regard to the nomenclature, as well as some points raised by the author. Primary, secondary and tertiary is reeled off to students, but it is not true. I have seen a case where there were two large chancres, no secondary eruption, and then catarrh of the ear developed and an eruption appeared on the eyes. I made a diagnosis of gummata of the iris, and some ophthalmologist agreed with me. So far as a herpetic chancre is concerned, that diagnoses itself. It is an interesting fact that in herpes, a syphilitic chancre developing on herpetic lesions, the herpes on pressure will produce a drop of serum and after waiting a few moments will give another drop, but the herpetic lesions will have but one drop.

I do not know what the last speaker meant by chancroid form of syphiloderma. We have a chancroid form of syphiloderma developed on the first chancre, which is the chancre redux, and any one examining the case closely will find all the characteristics of chancre. Of course, one who is experienced will make no mistake, but those who are not experienced, how will you protect them? I have seen a pseudo-chancroid which had all the characteristics of a chancre, and the patient had to wait four months to be certain that it was not syphilitic.

Dr. Isadore Dyer, New Orleans, in closing the discussion, said: I have only a word to say and that is I still wish to insist regarding the evident incorrectness in the differentiation of the types of syphilis. As a teacher of dermatology and syphilis I find it exceedingly difficult to gather any idea of syphilis from the text-books. They are misleading in their definition of exact types, which do not exist in the clinic, which I have not seen after an experience of twelve years in the practice of syphilis and dermatology. I have never seen the copper color in the early syphilide; I have only seen it follow an ulcerative lesion. I may not know what "copper color" is; if you speak of a raw-ham color, that means something to me, but I have never seen a copper color in a macular syphilide, nor has the student in my clinic seen it.

AN INTERESTING CASE OF LUPUS VULGARIS.*

R. R. CAMPBELL, M.D.
Professor of Skin and Venereal Diseases, Chicago Policlinic; Associate Dermatologist, Staff Cook County Hospital, etc.
CHICAGO.

The patient who furnished the subject of this short paper was referred to me by Dr. Henry Burwash of Chicago. The history of the case is as follows:

Mrs M. W., aged 53, Canadian; married fifteen years; no children; was never pregnant; had never been robust, but enjoyed fairly good health; never had a blemish of any kind or character on the skin until the age of 48 when, three months after an operation for the removal of some polypoids from the nose, she noticed a small nodule on the left cheek. About this lesion soft papules continued to appear for three years, when ulceration commenced in the original nodule. The ulcerative process spread peripherally until two thirds of the cheek had become involved in the destructive process, as attested by marked scarring and some ulceration at the time the patient came under my observation. There were also present a nodule on the right cheek and several nodules in the neck and throat, with marked enlargement of the sublingual and submaxillary glands on both sides These enlarged glands had persisted for over four years, without any evidence or appearance of pus One brother died of consumption twenty years ago, our patient having cared for him ten months previous to his death. Two aunts, on both the mother's and father's side of the family, died of consumption The patient's mother and father, however, are still living and enjoying good health

COMMENTS ON THE CASE.

The points of special interest in this case, to my mind, are:

1. The age at which the disease developed.
2. The enlarged lymphatic glands.
3. The possible sources of infection, namely, from her tubercular brother, or at the time of the operation on her nose.
4. The differential diagnosis between lupus vulgaris and tuberculosis verrucosa cutis.

Our ideas regarding lupus vulgaris have undergone radical changes during the past quarter of a century We have passed through a heated controversy regarding the nature of the disease, and Kaposi and his followers, who contended that lupus vulgaris is not tuberculosis, are, I am convinced, ready to acknowledge that this question is no longer a live issue. Most of us were brought up in the belief that the disease invariably begins in childhood. We have lived to learn that there are exceptions to this rule. The disease may develop at any age of life. Our text-books of to-day are much less positive on this point than they were a few years ago. Elliott[1] has reported one case and cites five other cases of the disease which developed in adult life. We have become accustomed to looking on lupus vulgaris as true tuberculosis of the skin, and tuberculosis verrucosa cutis as tuberculosis by inoculation. This distinction is a convenience in teaching, but we, as specialists, must recognize the fact that it is far from being accurate. Lupus vulgaris may be produced by inoculation and it may be produced by a transformation of other forms of tuberculosis.

A few months ago a boy was presented to the Chicago Dermatological Society by Dr. Pardee with a large ulcer on the cheek, from the surface of which luxuriant granulations were growing. The members present agreed on the diagnosis of tuberculosis, but not of lupus. Of the various forms of tuberculosis which were suggested as a possible diagnosis, that of scrofuloderma was the one in which I concurred. Scrofuloderma, as Jadasohn[2] states, is a subcutaneous tubercular deposit, the skin covering which has been destroyed by ulceration, leaving a denuded surface from which fungous granulations spring up. In this case, after treatment with the x-rays, the granulations disappeared, leaving a scar. When the case was presented to the society a second time typical lupus nodules were present in the scar tissue. In my judgment it was a case of transformation of scrofuloderma into lupus vulgaris.

Fabry[3] states that he has observed this transformation of scrofuloderma into lupus vulgaris. He has also seen a tubercular gland suppurate, discharge, the fistula heal and lupus develop in the skin adjacent to the scar of the fistulous opening; where the fistula closes such cases may easily be mistaken for primary lupus vulgaris with secondary glandular enlargement.

He further states that he has seen tubercular dactylitis produce lupus as well as tuberculosis of the bones and joints. Crocker[4] says that Jadasohn reports a case in which lupus developed in a tattoo-mark, caused by wetting the India ink with tubercular saliva; also one in which a tubercular ulcer of the finger in a butcher, caused by inoculation, produced lupus at a point higher up on the extremity.

Dubois Havernith[5] says: "Inoculation by continuity of tissue is frequently observed at the mouth of fistulæ, occurring in connection with tuberculosis of the joints and bones and lymph glands which have suppurated and opened spontaneously or have been cut into by the surgeon."

In a large number of cases it will be found that the disease has originated in some wound (abrasion or scratches), or in some anterior disease, as erysipelas, eczema, a blister, an irritated pimple and the like, pointing clearly to inoculation. Lupus nodules occurring early in a vaccination scar are presumably the result of inoculation of tubercular virus present in the vaccine.

Havernith cites an instance in which a girl who slept with her sister, who was affected with lupus vulgaris of the left cheek, acquired a lupus of the right cheek, which she habitually laid against her sister's face.

These facts are cited simply to show that because the only explanation which we can offer as to the manner in which our patient contracted the disease, namely, at the time of her operation on the nose or by nursing a brother suffering from pulmonary tuberculosis, does not exclude lupus vulgaris as a diagnosis.

DIAGNOSIS.

Clinically, we concluded that our case was lupus and not tuberculosis verrucosa cutis for the following reasons:

1. The rapid development of the disease.
2. The fact that the lesions present were not the waxy-like lesions of tuberculosis verrucosa cutis.

---

[4] Diseases of the Skin, third edition, p. 774

[5] British Journal of Dermatology, 1891, p. 360

3. Because the brown spots of beginning lupus were present.

There were no typical velvety, waxy nodules of lupus present at the time the case was under observation, but it is not uncommon to find them absent in typical cases when the patient first comes under observation. The lesions present were all such lesions as may be seen in lupus. We must endeavor to recognize and diagnose the atypical as well as the typical cases, and at the same time not lose sight of the fact that we have what may be termed border-line cases.

HISTOLOGY.

Histologically, the case showed the structure and the deep-seated location of lupus. As is well known, the lupus nodule is deep seated, while the lesion of tuberculosis verrucosa cutis is superficially located.

Stelwagon[6] shows an excellent cut of tuberculosis verrucosa cutis, taken from one of Bowen's cases, which shows the downward prolongation of the rete pegs and the superficial location of the disease, which was not the microscopic findings in our case.

By inoculation is, to my mind, the most frequent manner of contracting lupus vulgaris in adult life.

The enlargement of the lymphatic glands in connection with lupus may be due to surface infection, but, as Leloir has shown, it may also be due to the presence of tubercle bacilli in the gland. The non-inflammatory character of the enlarged glands in this case, and the length of time they had existed, rather impress me with the opinion that they were tuberculous. The lymphatic glands which were enlarged were situated on each side of the chin in the neck, indicating that absorption had occurred through the superficial facial lymphatics.

That tuberculosis of the skin is contagious in a greater or less degree there can hardly arise any doubt. In view of this fact it is well to follow the suggestions of Neumann,[7] who believes that inoculation of children and others by persons with tuberculous lesions on the skin or adjacent mucous membranes is more frequent than is generally recognized. In one place he observed four cases in one year of tuberculous lesions of the penis in children who had been circumcised. Tuberculous lesions of the upper air passages, as well as of the face and mouth, may inoculate others with tubercle bacilli by intimate contact, especially active and passive osculation. He urges scrupulous care in regard to disinfection of articles used by persons with any cutaneous tuberculous affection, scrofuloderma, etc., and regards cutaneous tuberculosis as, in fact, a more threatening source of infection than pulmonary tuberculosis, for the reason that its tuberculous nature is so often unrecognized. Dressings used by persons with tuberculous lesions of the nose, vulva, vagina or uterus, etc., scrofuloderma, miliary tuberculosis and lupus should be burned at once and attendants should frequently disinfect their hands.

414 Marquette Building.

DISCUSSION.

Dr. J. H. Duncan, St. Louis—From the description of Dr. Campbell's case I could not help thinking there might be a mistake in the diagnosis. I could not make up my mind that it was a typical case of lupus vulgaris, but rather some other tubercular condition of the skin. I learn that there was a difference of opinion as to the character of the case when it was presented to the Chicago Dermatological Society.

Dr. Joseph Zeisler, Chicago—I should like to use this occasion to emphasize that dermatologists should be exact in their diagnosis of cases which fall under the generic term of tuberculosis of the skin, pathologically speaking. I long ago joined with those who look on lupus as an absolutely classical manifestation of tuberculosis of the skin. But with others, I recognize a great many other forms of tuberculosis of the skin, many of which have been mentioned in this paper and which are clinically totally different from lupus. Yet, we still see a great deal of slipshod use of the term tuberculosis of the skin, which, in the last ten or fifteen years, has become to many what we would call in German "eine Eselsbrücke" (*pons asinorum*). In other words, it is used by a great many to cover up their unfamiliarity with clinical dermatology when a distinct variety of cutaneous tuberculosis should be specified. Particularly is it necessary, it seems to me, to retain the term lupus for all those forms of tuberculosis which belong to the classical type we have all learned to recognize as lupus, a disease which begins in early life and is characterized by deep-seated, brownish nodules, which may retain their condition for many years. A diagnosis of lupus is often made not in harmony with this clinical picture. The fact Dr. Campbell has pointed out that his patient acquired her trouble at the age of 48, or something like that, would not necessarily confuse me. I have formerly believed and taught that lupus always begins before puberty, but that can not be maintained at the present time; we certainly see cases of true lupus which begin later in life. I would not question the Doctor's diagnosis on that account. I was somewhat surprised that Dr. Campbell found it necessary to differentiate his case from tuberculosis verrucosa cutis. To my mind tuberculosis verrucosa cutis is distinctly confined, as a rule, to the backs of the hands and fingers, and I could not gather from his description that there was that peculiar wart-like condition or small stalactite prolongations from the skin which I would consider necessary to make that diagnosis. In conclusion, I wish once more to urge the need of retaining the different varieties of tuberculosis of the skin under distinct clinical names rather than to make it too easy for us by grouping all of these cases under the generic term of tuberculosis.

Dr. Henry G. Anthony, Chicago—I agree with Dr. Zeisler that we must maintain very strictly our divisions, and that we must look on lupus as a distinct type to be separated from everything else. Further, I agree with him that it has heretofore been used in a loose manner very frequently.

I had an opportunity of seeing Dr. Campbell's case. It was shown before the Chicago Dermatological Society. Some of those present made a positive diagnosis of tuberculosis verrucosa cutis and disputed the diagnosis of lupus. I was interested in the histologic picture the case presented, I therefore obtained from Dr. Campbell some of the tissue and studied it with care, comparing it with a section from tuberculosis verrucosa cutis, and it corresponds with lupus in every way.

Dr. R. R. Campbell, Chicago—In answer to Dr. Duncan's criticism, I tried to clearly set forth that no claim was made that it was a typical case of lupus vulgaris, but that we should be able to recognize and diagnose atypical as well as typical cases; furthermore, that we must recognize that we have borderline cases.

Regarding the suggestion of Dr. Zeisler, I question if tuberculosis verrucosa cutis should come into consideration. It was brought up at the meeting of the Chicago Dermatological Society, and Dr. Zeisler himself at that time suggested that we must look for the cause of the infection, that while he concurred in the fact that it might be a case of lupus, and probably was, yet he would like to know where the infection came from, as it was unusual to find the disease beginning at that period of life. As to tuberculosis verrucosa cutis occurring only on the backs of the fingers, we have exceptions to that rule. I have in my practice now a case of tuberculosis verrucosa cutis of the fingers and over the patella, and several months ago I discharged as cured a case of tuberculosis verrucosa cutis of the buttocks, referred to me by Dr. J. B. Murphy of Chicago, to be treated with the *x*-ray. I think we should be cautious about laying too much stress on the classical seats of diseases.

THE STUDY OF PEDIATRICS:

IS IT WORTH THE ATTENTION IT GETS, AND DOES IT GET THE ATTENTION IT DESERVES?*

C. F. WAHRER, M.D.
FORT MADISON, IOWA.

The subject of my paper consists in two questions that seem antithetic to each other, and I ask these questions in the same spirit that evoked the old and trite saying, as true as it is old, "Whatever is worth doing at all is worth doing well." If the symptomatology, etiology and treatment of the diseases of early and adult life were precisely alike there would be no need for the special study of pediatrics; but they are not alike, as they *differ often* in their pathology, yea, even in their anatomy, to such an extent that good treatment for a given disease in an adult would be bad treatment for a child. Again, some diseases that in childhood are very severe and correspondingly fatal, in adult life are extremely mild or do not appear at all or at least are rare, and the converse is exactly true of others. So the reason for the Section on Diseases of Children, in which their ailments are especially studied, is clear enough.

Now, is the study of this class of diseases worth the attention it gets? Some say "No," because it would not pay a man, except in the very largest cities, to confine his practice to children exclusively; he could not make a living at it. Now, for sake of argument we admit that, and while doing so ask another question—a habit we acquired when a small boy—namely, "What per cent. of the general practitioner's work is among the children, namely, all his patients from birth till their eighteenth year of life?" And further, "How many times has he made his entry into a good family's practice because baby was sick?" I hazard the answer that by far his largest income is derived from that source, both directly and indirectly. Directly because there are more children than adults; not so much among the 400, but, thank our luck, among the 400,000; and secondly, because children are more frequently sick than adults, even were they of equal numbers.

Another reason that might be adduced is that most parents are more solicitous about their sick children than about themselves, and that physician who can successfully cope with children's diseases can most easily find the way to the mother's heart, which is the golden key that unlocks the door that gives you entry to the whole family. Parents will risk their lives, or all they have, when their children are in danger. A mother, especially, would rush into a burning house if she thought one of her children were in it, and she would not question for a moment concerning her own danger. Likewise when a child is sick, she will send for medical aid much sooner than if she herself were ailing. She will also readily detect the skill, or want of it, of the physician called, and if she is convinced of his inability in treating her baby, she will have very little confidence in him hereafter for any other member of the family no matter how skilful he may be in other branches of the medical art. It is very foolish, and worse than silly, even criminal, for some general practitioners to assert, as one frequently hears them do, that any old lady who has raised a family of children can do more for a baby than any doctor; that children do not need any medicine, anyway that they are very difficult to treat, because, lacking intelligence in direct ratio to their youth, they can not give you any information as to their subjective symptoms, and if old enough to give information, it is likely to be faulty and misleading, and a lot more such fallacies and twaddle. I should be ashamed of my profession and doubt my own conscience were I to make such admission to anyone, and even if I felt that way it would be all the greater an incentive to study the ailments of early life all the more for feeling the want of proper information on this most interesting and valuable part of a medical man's knowledge.

If, as one of our older authors has said, "The child is father of the man," I hold it is equally true that pediatrics is the mother of general medicine.

Because a small boy has not achieved greatness or distinction, and he is only a street gamin, or perchance, even a child of unknown parents, it is not considered as much honor to treat him as it would be later on to treat this same person after he is the judge, the colonel or the general, the governor, or his excellency the president, some distinguished literateur, statesman, prince or potentate. It is no sign, nor does it logically follow, as the day follows night, that the study of pediatrics is less dignified, less distinguished, than that of general medicine.

The man who recently gave an example of his bloodless reduction of congenital hip dislocation is a pediatrist from the nature of his work and its limitations, and yet he received more notoriety from both the professional and lay press than any dozen or more of the other members of the medical specialties, either at home or abroad. He has shown us that there is an honorable and useful field open in this department, and I desire to remark, there is yet much unexplored territory that awaits others who will take the pains to investigate, and their labors will not go unrewarded, neither financially nor otherwise.

As I do not intend to go at this proposition polemically, I will say in the affirmative, that the study of pediatrics is worth all the attention it gets and far more.

This assertion almost covers the answer to the second question, "*Does it get the attention it deserves?*" So I will prefix my answer to my remarks on this part and say at once that it does not get the attention it deserves. In the first place, it does not get its proper attention in the medical college where it is claimed to be taught, but is not—or at least if so, only exceptionally.

In very few medical schools, either abroad or in our own country, do they have a special chair for teaching diseases of children, but it is usually taught by an associate or adjunct professor to the chair of internal medicine, and probably one lecture a week or every two weeks is devoted to it, and what is worse, not always is this chair filled by some distinguished man, but by one who is cutting his eye teeth preparatory to masticating the bigger chunks to be bitten off later. Frequently the student is given to understand, if not directly told, that the subject is of minor importance, and he would better give his special attention to pathology, bacteriology, obstetrics and gynecology, where his especial attention is directed to tubes, ovaries, hysterectomies, appendices and other glittering promises of surgical paraphernalia, fame, wealth, success, where, like military heroes, he can "wade through slaughter to a throne."

Of course, these are all necessary, but of how much use are they to the average tyro in practice? That comes later, after the baby has had a convulsion, or midnight croup, and thus introduced him to the favorable notice of the family.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

When I studied pediatrics I was taught it by my professor of chemistry, toxicology, materia medica, therapeutics, hygiene, state medicine, diseases of women and children. See? All one man, but he was versatile! Yet I am still at a loss, that of the many subjects he was professor of which of these he taught me most, but I am sure it was not pediatrics. If I know anything about that I learned it later. I learned much of it right here in this Section, from the papers I hear read and discussed (and which I reread later in The Journal), which were written by many of the distinguished authors who think it not beneath them to cast their lot with us. Now, while I am talking about its teaching in our medical colleges, I wish to assert my opinion, that aside from having special books on diseases of children, it were well to learn this matter by comparison. For instance, when a given disease is discussed in a treatise on internal medicine, its etiology, clinical history, pathology, anatomy, diagnosis, prognosis and treatment, it would be well to remark of its behavior in childhood, where it is similar or dissimilar from its manifestation in adults, and by these means much good were done to rivet the attention of the student to this important branch of medicine. Some authors do this in part, but most of them do it in a half-hearted way. I am sure if it were done as I fancy it should be done it would save much separate study, much book buying and reading over and over again in ponderous tomes and voluminous cyclopedias, which often reminds one of threshing over an old straw stack for the sake of a few grains of good wheat one might find. It were far more profitable to go to the flour bin at once.

Again, I want to draw your attention to an expression now principally used as an echo of the past, namely, the term "family physician." When you analyze this expression you will easily find it relates mostly to the man who treats the children of the family. While in general practice it often becomes necessary to call in some specialist, one who truly has made special study of a particular class of ailments, yet the family physician gets to see, diagnose and treat these cases first. Whether it be a mastoid trouble, a middle-ear disease, a sigmoid sinus thrombosis, a laryngeal croup, where intubation or tracheotomy must be done, an appendicitis that must be operated on, a fractured skull elevated or resected, or what not—no matter, the family physician sees most of them first, and he should be capable to diagnose and treat, or know fully when his work and knowledge need be supplemented by the proper special assistance; this in itself is no small accomplishment. When this state of things comes to pass, that is, when all medical men learn more of pediatrics and give it more of the attention it so richly deserves, then

> The air so full of farewells to the dying,
> And mourning for the dead;
> The heart of Rachel, for her children crying,
> Will not be comforted.

will find less application than of old.

After the loss of one of his children the poet Longfellow said:

> There is no flock, however well attended,
> But some dead lamb is there.

And yet I think if we knew more of the ailments of our little ones there would not be quite as many dead lambs, and angels would have to be recruited from older candidates.

And now, not only to the Section of Pediatrics, but unto all departments in medicine do I quote:

> Ah, what would the world be to us,
> If the children were no more?
> We should dread the desert behind us,
> Worse than the dark before.
> What the leaves are to the forests,
> With light and air for food,
> Ere their sweet and tender juices
> Have been hardened into wood,
> That unto us are children;
> Through them we feel the glow,
> Of a brighter and sunnier climate
> Than reaches the trunks below.

To you, my fellow workers in this section of God's vineyard is dedicated this sentiment: "The study of pediatrics is worth all the attention it gets, and it does not get all the attention it deserves." "Go ye into all the world and preach this gospel."

1007 Fifth Street.

DISCUSSION.

Dr. W. F. Boggess, Louisville, Ky.—That pediatrics is a subject that has been woefully neglected in the past we will all acknowledge, and it is undoubtedly true that it is a subject which appeals to all of us in the medical schools. If I can teach two facts each year to my medical students I feel that my labor has not been in vain. One of these is, that the diseases of children constitute an individual study. We have just heard of the wonderful disturbances of nutrition in children, and the differences in the development of the nervous system of children and adults. The future men and women will depend on the health of the children, and if we do not take care of our children along the special lines we need not expect future generations to be healthy. The other fact is that the students are to be impressed with the utmost optimistic views in the treatment of diseases of childhood. We have the most occult diseases to deal with, and the most profound disturbances to recognize, with but little help from the patient. We have unknown quantity as to the resistance and recuperative power. We know, nevertheless, that by proper treatment we can often bring back the most discouraging cases to perfect health and hardihood. The schools, I think, are waking up to the fact that we should no longer turn over this very important subject to an assistant, and that the subject is worthy of a full professorship—indeed, should have several professorships, for it is one we can not teach too thoroughly.

A CASE OF PROBABLE GUMMATA OF THE LIVER IN A CHILD OF SIX.*

MAURICE OSTHEIMER, A.B., M.D.
Instructor in Children's Diseases, University of Pennsylvania; Physician to the Children's Dispensary, University Hospital; Physician to the Medical Dispensary, St. Christopher's Hospital for Children.
PHILADELPHIA.

The case which I have the honor to report is that of a girl of 6, rather small and thin, but, according to her mother's account, always well except, temporarily, during attacks of measles and whooping cough. Her parents are both living, but are generally intoxicated; if only one be found, the other is probably "off on a spree." The father is a steady drinker and contracted syphilis about twenty years ago. Out of thirteen pregnancies, seven of which terminated by abortion, but two children are still living, a healthy man of 23 and this little girl. The others died between 3 and 10 years of age from various causes. No history of tuberculosis was obtainable.

The patient, who was not living with her mother, was first brought to the dispensary of the University Hospital, July 21, 1902. She had complained of pain in her right side two weeks before; this had been followed by slight fever, nausea, vomiting and jaundice. She was constipated and her passages were clay colored, but there was no pruritus. During the four days of fever, her highest temperature was 100 F. As she had failed to improve, she was brought to the dispensary, where examination showed a small, thin child, greatly jaundiced, the conjunctivæ deeply icteric, with prominent superficial veins of the chest and abdomen. The liver was freely palpable, reaching nearly 4 cm. below the margin of the ribs in the median line. There was at this time no tenderness or ascites. The spleen, while slightly enlarged to percussion, was barely palpable. Heart and respiration were normal. There were no traces of the keratitic, iritic, bony or cutaneous lesions of hereditary syphilis. Nor had she Hutchinson teeth, as the second teeth had not yet appeared.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

While her symptoms suggested acute catarrhal jaundice, the history, in spite of the absence of any other characteristic physical signs of congenital syphilis, pointed so decidedly to a probable syphilitic condition that protoiodid of mercury (gr. 1/12) and sodium phosphate (ʒ j) were given four times a day. On this she began to improve, the bowels became regular, nausea and vomiting ceased, and there were no more fever and much less jaundice when she was seen again, July 28.

Some days later, though this treatment was continued, swelling of the abdomen was noted. This gradually increased for about ten days, when she was admitted to the hospital (August 14). The fact was then elicited that treatment had been stopped over a week before admission. Examination now showed a very prominent abdomen, making the extremities seem much emaciated in comparison. There was no doubt of the presence of ascites, movable dulness in the horizontal position reaching to a circular area around the umbilicus, about 4 inches in diameter. There was pain in the right side of the abdomen, with evident tenderness on both sides. Careful examination showed excessive tenderness over the liver, in the midclavicular line, about midway between the umbilical line and the margin of the ribs, extending nearly to the edge of the ribs. On account of the ascites, the liver was not plainly palpable, while attempts to feel it produced great pain. No visible apex beat was found, and cardiac dulness seemed smaller than normal, probably from upward displacement of all the viscera due to the ascites. A faint systolic murmur was audible, heard best just above the apex, with marked accentuation of the second sound near the aortic cartilage. The lungs appeared normal. There was no edema of the face or extremities, no pleural effusion, nor any suspicion of cyanosis.

The ascites gradually diminished on milk diet, gray powder and potassium iodid (āā gr. ij, three times daily), with Basham's mixture and sodium sulphate (āā ʒ ij, daily). Examination two days later showed that the liver, now palpable, was still somewhat enlarged, though not so greatly as at the first examination, over three weeks before. Its lower margin was felt 3 cm. below the edge of the ribs, and a somewhat tender, nodular area was now distinctly palpable, about the size of an acorn, midway between the umbilical line and the margin of the ribs, in the right midclavicular line, continuous with the surface of the liver. The spleen was not palpable, though still slightly enlarged to percussion. Urine analysis showed traces of albumin, together with a marked indican reaction. From 16 to 32 ounces of urine were passed daily, and the improvement continued, jaundice and ascites rapidly diminishing. As these had both disappeared by August 24, all medication except the antisyphilitic treatment was stopped, and her diet was increased. The nodular mass in the liver was no longer so plainly palpable, and the liver had decidedly diminished in size. Two days later she was out of bed for the first time, and left the hospital in excellent condition September 3. Her liver seemed of normal size at this time, reaching almost 2 cm. below the margin of the ribs in the median line. She was given specific treatment, to be continued during one week each month. This was carried out until Christmas, 1902. Since that time she has had no treatment and has kept perfectly well.

From the course of the disease it seems that this affection of the liver, undoubtedly syphilitic in nature, should be grouped among the manifestations of late hereditary syphilis (syphilis tarda). The family history shows the presence of syphilis; and the fact that early signs of congenital syphilis were not noticed in the child can probably be explained by the lack of attention which she received on account of the usual intoxicated condition of one or both of her parents. Some characteristic symptoms were probably present in early childhood or infancy, though they passed unperceived. The excellent results on antisyphilitic medication tend to prove that this hepatic condition was syphilitic in nature.

But few such cases have been published. In fact, syphilitic hepatitis, while common in infantile congenital syphilis, is rather rare among the manifestations of late hereditary syphilis. Outside of the case reported by Dr. D. L. Edsall,[1] which, as his resident physician, it was my privilege to study, I have been unable to find more than one other case of gummata of the liver in late childhood in the literature of the past twenty years, that of Barth.[2] Very few comprehensive articles on the manifestations of late hereditary syphilis are to be found at all, and reports of cases are rarer still. Fournier[3] devoted an entire volume to them, while Barthélemy,[4] in 1884, was able to collect but 30 cases of late congenital syphilis occurring in patients ranging from 2 to 34 years of age, confirmed postmortem. In but 6 of these patients were gummata of the liver the only lesions found at autopsy, while in 13 there was marked interstitial hepatitis beside the gummata. Hudel's extensive monograph on syphilitic hepatitis, quoted by Holt,[5] was unfortunately unattainable. In 1890 he was able to collect only 47 cases of late syphilis of the liver, including those of Barthélemy.

Edsall's case occurred in a girl of 14, whose only signs of congenital syphilis were deafness, ozena and scars from an ancient keratitis. There were dyspepsia, headache, dyspnea, loss of flesh, edema of the face and extremities, anasarca, double pleural effusion, ascites and two large, hard, nodular palpable gummata of the liver. She was sent into St. Christopher's Hospital for Children with the diagnosis of sarcoma of the liver. Her spleen was also somewhat enlarged. There was albuminuria, but no fever at any time. On mercurial inunctions and potassium iodid the masses disappeared in two months, yet the liver remained hypertrophied and hard. A year after discharge from the hospital examination showed a completely normal liver. A somewhat similar case, in a girl of 15, has been reported by Barth, with postmortem confirmation. Delbet[6] reports an interesting case of gummata of the liver in a child of 2½ years, with ascites and slight jaundice, on whom laparotomy was performed for a supposed malignant growth. Recovery followed.

The pathology of the late hepatic manifestations of hereditary syphilis has been discussed by Barthélemy, Fournier and Hudelo. Barthélemy finds the form in which there are only gummata very rare, while that containing gummata with diffuse interstitial hepatitis is more frequent. Fournier[3] considers diffuse interstitial hepatitis the most common form of late hereditary syphilitic hepatitis, cases of which have been reported by Engel,[7] Depasse[8] and Créquy. Fournier states that gummata, when present, are, as a rule, only found at autopsy. Therefore, a hypertrophied liver, cured on antisyphilitic treatment, may have contained gummata which, perhaps, were situated where they could not be palpated. Thus it is more correct to consider both forms together, the gummatous and the diffuse interstitial hepatitis. Rarely the hepatitis may be amyloid.

Fournier considers jaundice an unusual symptom. Henoch[10] considers both icterus and ascites rare with syphilitic hepatitis. Beside the irregular enlargement of the liver, the spleen is usually somewhat enlarged, and albuminuria points to some renal involvement. Baginsky[9] reports the case of a boy of 4 with keratitis, followed later by swelling of the left lobe of the liver with ascites, slight icterus and hematemesis. In most textbooks the subject of hepatic affections in hereditary syphilis receives but scant attention. Osler,[11] Holt and Gerhardt[12] mention the occurrence of gummata of the liver in late hereditary syphilis; Comby[13] notes the occurrence of diffuse interstitial hepatitis with gummata, ascites and pain.

The diagnosis is not difficult when other characteristic signs of hereditary syphilis are present. Yet, as Edsall states, these cases are generally mistaken for malignant growths of the liver. Fournier believes that many cases of gummata of the liver escape attention because they usually run a symptomless course. Edsall also refers to the possibility of calling the condition leukemia or splenic anemia. Henoch, in his large experience, has never seen a case of late hereditary syphilis. He believes that many of the cases described by Barthélemy were simply chronic interstitial hepatitis from some other cause. This is evidently not the case, however, as the existence of this condition has been proved by pathologic examination. Engel calls attention to the predominance of the female sex among the few cases of late syphilis of the liver reported, in all less than 50, including the cases both of diffuse interstitial and gummatous hepatitis, as manifestations of late hereditary syphilis.

It is, of course, possible in this case that the syphilitic affection may have been acquired and not congenital. But the family history is so decidedly typical and the possibility of the early symptoms having passed unperceived so perfectly probable that it seems unnecessary to search for further explanation. The presence of the distinctly palpable node on the surface of the liver also excludes simple hypertrophic cirrhosis, for which, besides, there was no known cause. Though such cases are rare, they probably occur more frequently than is commonly supposed, passing unperceived or being mistaken for malignant growths of the liver. From the standpoint both of diagnosis and treatment these cases are most important, since, even though syphilis only be suspected, specific treatment deserves a trial and may effect a cure.

My thanks are due to Dr. J. P. Crozer Griffith for the privilege of reporting this case. The patient was under treatment on his service last summer during his absence from the city.

DISCUSSION.

Dr. R. B. Gilbert, Louisville, Ky.—Late syphilis of the liver is certainly very rare; I can only recall two cases in my experience, and these were rather recent. The first of these cases was very much like the one reported in the paper. It occurred in a girl of 5 years, and the ascites was enormous and proved most rebellious to treatment. After some hesitation I tapped the child and took away a little over one gallon of fluid. After this medicine seemed to have some effect, but the fluid accumulated again very rapidly, necessitating another tapping in about ten days. After this she improved steadily, and under mercury and iodid of potassium was restored to full health. The other case was a female infant of 18 months, with an abdomen so enormously distended that breathing was greatly impeded. I drew off from this child over one quart of fluid with great relief to the little one. This was only a few days ago, but I expect a good result. The paper has greatly interested me because several clinicians criticised me severely in connection with my first case, and advised against any radical or heroic treatment.

Dr. C. F. Wahrer, Fort Madison, Iowa—I often wonder how much hereditary syphilis complicates many of the diseases of childhood or masquerades under the guise of some other disease. I have felt that when in doubt mercury or iodid of potassium, or both, should be given.

Some time ago I was called to a little girl of 4 years who was supposed to be in danger of dying. I examined the child and found a weakness of the heart, but none of the classical symptoms of any special variety of organic disease. The child had had none of the diseases usually causing disease of the heart, yet the heart muscle was weak and the innervation of the heart appeared to be disturbed. I privately inquired into the previous history of the patient, but obtained no information. I was subsequently called to see two other children in the same family who were similarly affected. Finally the mother came to me to be treated for syphilis, and then she told me that her husband had contracted syphilis some years before, and had been improperly treated. I then learned that two of her children had presented evidences of syphilis and had died very suddenly after birth. I accordingly put the whole family under treatment, and three years later the mother gave birth to a child, who now, at the age of 8 years, appears to be perfectly free from syphilitic taint. Since this medication the other children have had no more attacks of heart trouble.

IS THE REALIZATION OF REASONABLE IDEALS IN DENTAL EDUCATION NEAR AT HAND?*

CHAS. C. CHITTENDEN, D.D.S.
MADISON, WIS.

Reasonable ideals in dental education would seem to be defined by those standards as yet unattained and not yet in practical working, but which are admittedly possible and desirable in the estimation of the leading dental teachers, practitioners and examiners of this and foreign countries as expressed and promulgated by them personally and in the councils of the great national and international organizations. In no other country in the world is dentistry esteemed so truly a separate and distinct science and profession as in the United States of America.

Most of our schools are independent of and free from domination by the medical profession and medical schools, which is a condition not at all to be found in the schools of Europe, where our beloved profession is held as a mechanical art tacked onto a background of medical didactics.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

Every enthusiastic lover of his profession probably has formed an ideal for himself, or for some one in whom he is interested, which should represent the summing up of his dream of educational perfection in dentistry, but the chief difficulty in the way of the general adoption of these ideals is, that they are as various as they are ideal. One man will urge that an academic degree is of main importance, preparatory to the study of dentistry at all, while another will insist that beyond the simplest of common school preparation the wisest educational prerequisite for dental college is found in a term of pupilage in the office of a successful practitioner where the study of text-books is a mere incident and the education is conducted on the principle carried out by the celebrated Mr. Squeers at Do-the-boys Hall, England, *i. e.*, teaching spelling as follows: "w-i-n win, d-e-r der, winder. Go and wash it."

And then there are all the intervening ideals that can be thought of, as wide in variation of detail and almost as numerous as the personnel composing the dental profession, and it will not be denied that there is fully as great a percentage of dreamers, cranks and would-be prophets and leaders among us as is to be found in any other calling. It is out of the multitude of counsel, based on actual experience and effort, that reasonable standards can be evolved. The educators and examiners have been each and all striving for wise standards, that will fill the educational ideals for some years to come, and also be practicable and attainable as a general fair minimum requirement by all educational institutions worthy the name. The dental literature for the past several years has overwhelmingly pointed to high school graduation and four years of special dental training as the minimum place where standards could be with safety set up and permanently established. The variations in standards for high school in different portions of our country are great. Indeed in some states having dental schools there is practically no established high school worthy the name. But like all other commodities schools accommodate their curriculum to the demand, and, at any rate, equivalents can be easily and fairly set up through the system of preliminary examination now in operation under the rules of the two national associations of faculties and examiners, so that the decision as to what is a reasonable requirement in high school graduation can be very easily attained. And even where there are elective high school courses to be had, it is but a matter of detail to elect and maintain a reasonable equivalent. The college course has been advanced for several years to three years for graduation, and the addition of the fourth year to the curriculum which is to be inaugurated in the present year in all our schools completes what may be properly denominated reasonable ideals in dental educational standards.

If all the schools composing the N. A. D. F. were departments of properly endowed universities, and thus relieved of the everlasting commercial handicap, there would be no question as to the immediate establishment of reasonable ideals. But the fact obtains that a large majority of them are practically struggling for existence and feel they can not be too particular in their standards.

Having fairly determined what should be demanded and established in standards the question arises, who shall establish and be responsible for the carrying out of these standards? The answer is, the colleges through their national associations and the examiners standing behind, protecting, insisting and encouraging by the official authority that is in them vested. This being accepted as the proper method, all obstacles that beset the path and intercept the attainment of the goal must be squarely faced, with the view to most directly overcome them or pass around them in the onward course. The men to be convinced and enlisted and the means, the employment of which will most likely and directly conduce to the ends sought, are important. What is the power that must be invoked?

For over forty years dental schools have been pursuing their steady growth in size of classes and in numbers without there having been set up a single fixed minimum educational requirement for beginning a school course that could be in any sense claimed to be an established prerequisite. The demand for skilled practitioners was so great during the period of phenomenal growth and development of this great country following the close of the Civil War that perhaps it was as well that this should have been so, but to-day the demand is not so much for mere artisans as for educated, scientific, professional—gentlemen, if you please —who shall be competent to take the helm and guide the destinies of a great profession that is more nearly an exact science than any other, except it be, perhaps, the law.

Attempts at the raising of requirements have been continuous, and the past five years have seen the establishment of two years' high school preparation, and the present year inaugurates the four year course. This advance up to date, in spite of the prediction of the pessimists and conservatists that putting up the bars would financially ruin the smaller schools, has been followed by an era of unprecedented prosperity to the schools, and when it has been honestly enforced the quality and character of the college output has been in the main materially improved.

The universities have been held back for years, hoping by slowly raising the educational requirements to enable the weaker schools to keep pace and so hold the national body together. It would seem that this has proved a mistaken policy, for the proceedings of the national association of colleges are filled with charges and trials, convictions and fines against school after school for the violation of the plain rules of the body as regards the receiving and giving standing to students taken into their classes, with no other earthly object apparent than to swell the income of the struggling institutions. This is, of course, human nature, but it is none the less scandalous, notorious and disreputable in the highest degree and should be branded with the condemnation of the profession at large.

A case in point of what is constantly going forward in the effort to swell classes at whatever risk (and the half of which is never brought to light) is that of an endowed university which was compelled to refuse admittance to its classes the present year to about thirty matriculants because they did not possess the prerequisite education for admission to the third year of high school, as required by the rules of the two national associations. These men applied elsewhere, and most of them, it is believed, are now enrolled in the classes of other schools belonging to the association.

Another instance is that where one school sought (and did in some degree succeed in its undertaking) to swell its own classes by sending out emissaries, cappers, or steerers, offering in wholesale lots to almost the entire classes of a competing school reduced tuition rates varying from $25 to $65 for the $115 advertised tuition fees.

Another instance of flagrant attempts on the part of schools in the full membership in the N. A. D. F. to evade the rules is where one of them, by the admission of its dean, has taken into its freshman class for regular work a number of matriculants who had signally failed to pass the preliminary examination (set up by the national association as its minimum standard for admission to classes) before the duly accredited appointee of the state superintendent of public instruction, and then attempting to build up some sort of excuse for its conduct by not only attacking the educational fitness of the examiner, who, by the way, is the honored principal of a district school in a large and flourishing northern city, but also by attacking publicly his character as an honest man and public servant, and thus attempting to excuse itself for having these men in its classes at all, even under the name of "specials" and "in our preparatory classes, besides doing regular freshman work." And this school is evidently banking on being able to control enough "inflooence" in the national association to cover up or else explain away its conduct or, at the most, escape with a "fine," as though payment of money could in any sense atone for the violation of the law of common honesty.

There is also the lamentable spectacle of schools posing as the very "ideal" of everything desirable and whose official heads are shocked and hurt at the mere suggestion that any one should presume to criticise them or question their reputability, that are constantly and persistently flooding the secular press of the country with paid pictorial advertisements of their classes, foot-ball teams, handsome, noted and extra-skilled teachers and instructors, exploiting the peculiar advantages of the institution and its professors over all competitors, all done in a style to put to the blush the common advertisers of the cheap "dental parlors" type.

Such things unchallenged and unrebuked certainly do not tend to the realization of ideals and most certainly do not offer incentives to enter our profession to the class of young men our profession most lacks. This is the sort of thing which has always stood in the way of the proper establishment and maintenance of ideal standards. It would seem if we are to establish ideals for practical use that the public stamp of condemnation should be put on such practices and the guilty institutions incontinently thrown out of the national organization and made a public example of.

It is futile for this body, composed of the membership of the "reputable" colleges of this country, to adopt for the government and conduct of its members certain rules and standards and methods of procedure based on high ideals of ethics and mutual protection, to be accepted by the profession at large as a criticism of the schools' reputability, and then devote a large part of its annual sessions to inventing excuses and apologies for flagrant and open violation of the letter or spirit, or both, of these standards and rules, thus giving to the outside world the very reasonable impression that the body is dominated by anything but the real spirit of building up ideals that their rules and standards would indicate. It is high time that the college association awaken to the realities of the situation. There is at this time, as a result of years of struggle and contention between schools and the examiners for the establishment of specific standards, accepted by the schools and made by the boards their measure of reputability—there is now, I say, a period of mutual accord and trust and peace between these bodies which should be the harbinger of better things to come. The schools are assured of protection by the boards from any infringement and violation by competing schools, made and provided that the college association will purge itself of the violators and enforce its own rules without fear or favor.

In order that ideals may be sooner and more surely established and maintained the boards of examiners, with all fairness and reasonable consideration for the interests of honest educational efforts, must, nevertheless, be mindful of their official oath to carry out not only the letter but also the spirit and intent of the law for the protection of the public. They must, in national association, stand squarely together on reasonable requirements and, more than all else, have the courage of their convictions in passing on the character of the colleges and their output, constantly having in mind that the goddess Justice does not close one eye and blink the other when on duty.

If the schools will rise to the occasion and set the pace the examiners will most assuredly help and sustain them in holding it steadily up. If N. A. D. F. will not purge itself and be honest in enforcing its rules there will be but one way to move the profession forward, to-wit, the better and honest schools will naturally unite themselves together and the examiners must join them in a newer and higher emprise on a surer and, it is to be hoped, better laid foundation.

DISCUSSION.

Dr. Eugene S. Talbot, Chicago—There is perhaps no one in the country so well posted on the management of dental colleges as the essayist. He is one of the foremost men who has been looking forward to the future of dentistry and has done a great deal in the way of legislation. He would have been here at this meeting but for the fact that the legislature is now in session and changes are being brought about in the state law in Wisconsin. He wished me to extend his thanks to the Association for its courtesy in having his paper read and regrets that he could not be present.

There is no doubt that there is a good deal of underhand work going on in some dental colleges. I know of three or four dental schools in which agents are sent out soliciting students. A percentage is paid these agents for procuring the students. There are many other glaring deficiencies in the methods of obtaining students. I was somewhat surprised that more was not said along these lines.

I understand it is the intention of the national board to bring this subject before their meeting for the purpose of discussion. I believe the time has arrived when the departments of dentistry connected with universities will have a large influence. Now that the universities have a method for the purpose of uniforming the education in all their departments and also for the purpose of raising the standard of qualification for admission to these different departments, the time is near at hand when the graduate of dentistry in this country will be on an equal standing with the graduates of other specialties.

Dr. M. H. Fletcher, Cincinnati—I do not know that I have much to say, except that I am interested in bringing about a higher standard of dental education. As a member of our State Board of Dental Examiners for five years, I have been greatly chagrined to know that our laws compel examiners to give such elementary questions. I would consider a first-course student in either dentistry or medicine below the standard if he could not pass such an examination. There is every reason, from my standpoint, for extreme effort in raising the standard, and no doubt such men as the essayist and those interested in bringing it about need the co-operation of all good men in this work. I sincerely trust that the day is not far distant when the standard of efficiency may be raised.

Dr. M. L. Rhein, New York—It goes without saying how much we are in sympathy with the elevation of the standard of qualifications for admission to a dental educational school. I feel personally that Dr. Chittenden made his paper a little weaker than he intended when he spoke of the smaller colleges being irretrievably hurt by the length of the course, because I feel very much on this subject as was expressed by Dr. Billings, the President of the Association, in his opening address, that the time has come when the smaller educational institutions must go out of existence. There is no use for them at the present time. I would even say that I think the idea of proprietary educational institutions is a mistake. I think this Section should come out flat-footed on the question of men enjoying a salaried position due entirely to the income of the institution with which they are connected. That has invariably been one of the worst features connected with proprietary dental education in this country. If the efforts to raise the standard of dental education is a blow at this sort of institution, it is a blow that is well merited and with which, personally, I am in full sympathy, because the sooner they are eradicated and destroyed so much the better for the interests of the country at large. How much better it would be if there were fewer institutions where there was a distinctive salaried position of an amount to enable the proper teacher to be selected irrespective of the necessity of earning their living by the practice of their profession. It is impossible at the present day for the real professor of any branch in a dental institution to be engaged in the active practice of his calling. His attention to practical dentistry should be confined to the infirmary division of the institution with which he is connected. That is the idea we have to look forward to in dental education. t makes little difference to my mind how much we raise the tandard, if we fail to accomplish the real results.

There is just one little point of difference that I have with Dr. Chittenden in his paper, that is, the words of criticism that he makes at institutions of character for keeping themselves advertised, as he says, in the eye of the public, advertising heir superiority over the smaller institutions. I hardly beieve, if I could talk this matter over with Dr. Chittenden, that he would see this in the light in which he appears to, judging from his paper. To my mind, it is one of the forms that is necessary to use to drive out of existence the inferior institution. It is impracticable, in my view, to compare any one of our great institutions with an advertising dental parlor; so, I think, Dr. Chittenden has made rather an unfortunate mistake in a comparison of this kind. These large institutions are constantly before the eyes of the public in the public print. A very necessary form of the education of the young men today is the athletic surroundings of the university. There are differences of opinion regarding their value, but at the present time they have the sympathy and the accord of the American people. I myself believe that they play an important part in the welfare of our educational institutions. I believe they do good, and can do harm. Devotion of time to them to the neglect of studies is the same evil which besets every young man in all surroundings of life. A great deal of the advertising of departments of universities is of such a nature as is not directly sought for by these universities. It is worked up by the individual parties, and I personally see no harm in it. I believe this is a sort of competition which will bring out better features from the opposite institutions.

Mr. T. Constant, Scarborough, York, England—I have so little knowledge of the condition of education in this country that I am hardly in a position to speak on the subject. At the same time, speaking generally on the question of education, a subject to which I have given some attention, I think the most necessary thing in considering the educational conditions of any kind is to insist on a very high standing of preliminary education. The time that is necessary to give to the application of technical knowledge, when the mind is very receptive, as in the case of medicine and surgery, and especially in dentistry, is so largely devoted to the requirements of special knowledge that one's general knowledge is liable to be neglected. I think, therefore, that prior to examinations of special studies, one's general education should be as complete as possible. I feel that the fewer educational centers we can have the better. The facilities for travel now are such that distances are not the consideration they used to be, so that one great objection to having centers of education is removed. I therefore think that great harm is done, and I believe from my little knowledge, particularly so in this country, by multiplication of centers of education. On the same lines I believe myself in the uniform standard of examinations. I think if all the states of America united and had one national standard in examinations to which it became necessary for every student to present himself before being licensed to practice it would be a good thing. He could then succeed in taking the ordinary university degrees. License to practice, I believe, should be determined by national examining centers.

Dr. W. E. Walker, New Orleans—I believe the idea of the formation of great universities with dental departments is the correct one, and that the working out of the plan as it is being done in Harvard is really what it ought to come to; that there should be the unification of preliminary requirements for all the different departments instead of having one for medicine and another for dentistry, the basal studies being taken alike by all, and capped by the special work according to the field a man intends to make his life work, though the fingers should have some training throughout.

The question of preliminary requirements is a very difficult one to handle. Because it was found that when the dean examined the students he was so influenced, not only by his desire for the college to grow, but by the forces brought to bear on him by other teachers, that he would sometimes admit students that ought not to be admitted, it was thought to overcome that by the requirement that the dean should no longer examine students for entrance, but that the state or county superintendent of education should have the matter in hand. The law does not specify whether it shall be the superintendent of the county in which the school is located or in which the student resides. The result is that there is a different standard. We find many boys coming from the country where the standards are low and where the county superintendent will allow himself to be influenced by personal feeling and give him a certificate which he would not have received had he come to the educational center to be examined by the superintendent of the county in which the school is located, where the standard would be higher. I have an instance in mind in which a student was examined and refused by the examiner of the county in which the school was located and went home and was passed by the superintendent of the county in which the student resided. There must, therefore, be some changes in that direction. Just how it is to be done I do not know. A national body to examine all applicants would probably work most satisfactorily.

Dr. Chittenden*—The only comments I would make in discussion of this paper on educational ideals is as to the object and intent of the paper itself. As you are all aware, I have most excellent opportunities officially to gather correct information concerning what is going on in the dental colleges, some of which is open to criticism and condemnation. It was my desire, in this unofficial way, to acquaint the profession at large with the irregularities, quibbles and sharp practices that are being used and which the schools themselves appear to have the idea are unknown and never to be known by the public. It has seemed to me there has been enough posing and not enough plain honesty of purpose. The paper only hints at a lot of abuses which have, to those watching closely, become offensive, both in practice and frequency of occurrence. It is time the profession at large is fully informed of the situation and given an opportunity to speak out, demanding reformation. The keynote to the condition referred to is, of course, commercialism. There is no question that if honesty could be placed before money interest in the conduct of all the schools for a single year, and standards put where they reasonably belong, that the commercial side of dental education would take care of itself, and financial interests involved be greatly benefited, and it is a great wonder that the educators cannot or will not see this fact. The intent of the paper in detail was to throw some flashlights in silhouette that would bring a quick, sharp understanding of the situation into view, and nothing said in it has been engendered by or intended to convey any sense of bitterness or unfairness to the schools themselves. I have reason to believe the National Association of Dental Faculties will be given an opportunity this summer to squarely meet this situation, and I most devoutly hope and pray, for their own and dental education's sake as well, that they may meet it squarely in the spirit of true professional honesty and singleness of purpose.

---

* Dr. Chittenden not being present, his paper was read by Dr. W. E. Walker, New Orleans, and these closing remarks by the author have been furnished subsequent to the session.

THE ABUSES AND USES OF VENESECTION IN THE PRACTICE OF MEDICINE.*

ROBERT REYBURN, A.M., M.D.
Dean and Professor of Hygiene and Preventive Medicine, Medical Department Howard University.
WASHINGTON, D. C.

Though for centuries venesection was considered one of the most valuable methods to be employed in the cure of disease, it has now fallen entirely out of use.

The present generation of physicians, indeed, has seen so little of the practice of blood letting as a therapeutic agent that it is hard for them to realize how universally it was used even as late as the middle of the last century.

At the time the writer commenced the study of medicine (about fifty years ago) the favorite text-book used by medical students was Watson's "Practice of Medicine." It was indeed a charming book, and one that for beauty of style and literary diction could not be surpassed. It was, however, in some respects a most discouraging book. Watson would give the most vivid pictures of the symptoms and progress of diseases and yet when it came to their treatment all diseases were apparently treated in nearly the same way. His favorite method for the curing of nearly every inflammatory disease was practically limited to the administration of calomel or other mercurials and the free use of bleeding and blistering.

As I read this book I used to ask myself: Is it possible that our means of treating the physical ills of our patients are limited to the use of the above three methods, and its seemed to me that if such was the case then the practice of medicine was a delusion and a failure.

Fortunately, about this time (1853) I procured a copy of J. Hughes Bennett's great work on clinical medicine. I received from that book a light and illumination on my studies in the science of medicine that I never had before.

Bennett was a great clinical teacher and reasoner, and while he used bloodletting in a moderate degree, yet he combined with it the literal use of nourishing diet and stimulants. Like the immortal Graves, he was far ahead of his time. Graves was the man who at a time when all the physicians of his time were bleeding and starving their fever patients, dared to feed those liberally under his care. Dr. Graves asked that when he died they should carve on his tombstone, "Here lies the man who fed fevers."

The picture given by Le Sage in his immortal book, "Gil Blas," of the character of Dr. Sangrado probably aided largely in calling attention to the absurdity and harmfulness of the free blood letting, so much used by the physicians of that day.

In Gil Blas there is one exquisite piece of satire that we must quote. During a time of great sickness and mortality the notary is sent for to make the will of a sick man. He immediately asks the question, who is the attending physician? On being informed that it was Dr. Sangrado, he at once says they must hurry and lose no time, for if they do not there will be no opportunity to make the will.

Physicians seemed in that day to regard the inflammations of an organ as a monster that had taken possession of the part and that could be destroyed by the abstraction of blood from the veins or by blistering and the [illegible]ration of mercurials.

The more accurate knowledge of our day (though still incomplete) has shown us that most, if not all, of the phenomena manifested in the course of the acute inflammations are due to the efforts of the organism to defend itself from the inroads of micro-organisms or the toxins produced by them. We know now, also, that no inflammatory disease can be suddenly cut short by any method of treatment. What we can do, however, is to guide it to a favorable termination.

Admitting, therefore, the utter failure of venesection as a means of cutting short or of curing acute inflammations, the question then arises, were our ancestors in the practice of medicine entirely mistaken in their practice of this now forgotten remedial agent? We should remember that this method of practice was employed by many of the brightest lights of our profession. The physicians of former times were just as acute observers of diseases as those who practice medicine now.

Have we then not lost something of value to our science in our entire abandonment of the practice of venesection? Are there not cases even now that would be benefited by blood letting, and have we not gone from one extreme to another in utterly abjuring it?

Arthur Helps, the great English essayist, says that when a man attempts to avoid error on one side he is very apt to fall into the opposite error. The pendulum of truth is apt to vibrate from the error on this to that of the opposing side.

There are now a considerable number of the members of our profession who believe that while the idea of cutting short an acute inflammation by blood letting is an absurdity, yet in certain diseases venesection is a valuable therapeutic measure, and in some cases is absolutely necessary to preserve the life of the patient.

VENESECTION IN CEREBRAL ENGORGEMENT.

The class of cases benefited by the abstraction of blood are chiefly those in which there is an abnormal blood pressure in the body which endangers the rupture of a blood vessel in the brain or causes a stasis of blood in some vital organ. Let me give an illustrative case:

Mrs. G., aged 56, was placed under my care a few months ago, for the following symptoms: First, a feeling of numbness of the right side of body, involving both upper and lower right extremities, persistent headache, more marked on left side; the headache increased in severity; then she felt very giddy on attempting to walk; her speech then became affected and articulation imperfect. On examining her, I found her to be a stout plethoric woman who had always enjoyed good health, and weighing about 170 or 180 pounds.

She had always been accustomed to living on a farm, and had usually been working a good deal in the open air. For about a year before I saw her, she had changed her occupation to indoor work. She was in fact during that period employed in taking care of an invalid lady and had remained a great deal indoors, very rarely leaving the house. She generally had enjoyed her food and had usually eaten a liberal supply of meat and nourishing food, and no doubt had partaken of more nutriment than her system needed.

Here was a plain case of threatened cerebral apoplexy, and she became very much alarmed (and with reason) as to her condition. Here was a woman past the menopause and having not the relief that menstruation might have given to the overfilled blood vessels, a woman suffering from a hyperemia with threatened fatal results on account of the degeneration of the cerebral blood vessels which to a greater or lesser degree must be expected at her age. Now would any physician hesitate to bleed in such a case as the above? The proper treatment in such a case is to bleed freely from the arm, twelve or sixteen ounces of blood, and follow this by brisk purging with saline purgatives and low diet. Such a case can be brought (as was this one) from the jaws of death by the proper treatment such as outlined above.

---

* [illegible] before the Medical Society of the District of Columbia,

BLOOD LETTING IN PNEUMONIA.

Another disease in which bleeding is sometimes necessary to prevent death is acute or croupous pneumonia. In its great fatality in our day acute pneumonia is a standing disgrace to the practice of medicine.

There can be no question that acute croupous pneumonia is worse treated and the percentage of mortality from it greater than it was thirty or forty years ago. This is admitted by all modern writers on the subject, and it will only be necessary here to give a few references to prove the above statement.

The nestor of American medicine, Dr. N. S. Davis,[1] says "the mortality in pneumonia has increased during the past forty-five years." The *Philadelphia Medical News* (March 6, 1897) says mortality from pneumonia has increased during the past fifty years. In New York City out of the 41,000 deaths occurring in 1896 5,383, or nearly one-eighth, died of pneumonia. The mortality from pneumonia in New York City hospital during the period beginning 1834 and ending 1843 was 25.4 per cent., during 1844 to 1853 25.7 per cent., 1854 to 1863 23.8 per cent., 1864 to 1870 27.7 per cent., 1877 to 1886 38.8 per cent., 1887 to 1895 34.7 per cent.

Dr. Putnam[2] of Boston says pneumonia mortality has increased 50 per cent. during the past thirty years. *American Medicine* (May 18, 1901, p. 277) says pneumonia is more fatal than tuberculosis. In New York City, from 1890 to 1900 there were 56,092 deaths from pneumonia and 50,490 during the same period from tuberculosis. In Chicago during the same period there were 25,228 deaths from pneumonia and 22,957 deaths from tuberculosis. The following extract is taken from The Journal of the American Medical Association (Jan. 24, 1903):

> THE INCREASING PNEUMONIA MORTALITY.
>
> Nearly three years ago we called attention to the fact that statistics showed that pneumonia was causing more deaths than tuberculosis. We believe that we were the first to call attention to this fact, but it is becoming generally recognized.
>
> The circular issued by the Health Department of Chicago for the week ending Jan. 17, 1903, begins with the statement: "Since the census year 1900 pneumonia has claimed more than one-eighth of all the victims of the Grisly Reaper in Chicago; one-third more than consumption, and 46 per cent. more than all other contagious and infectious diseases combined, including diphtheria, erysipelas, influenza, measles, puerperal fever, scarlet fever, smallpox, typhoid fever and whooping cough, the total of which deaths was 4,489 as compared with a total of 6,562 deaths from pneumonia." This statement is a striking one and certainly confirms our earlier assertions as to the predominance of pneumonia over other infectious diseases as a cause of mortality.

American Medicine (Jan. 31, 1903) says, concerning the mortality in Chicago, that during the first 17 days of January, 1903, more than one-fifth of all deaths was due to pneumonia. The deaths from tuberculosis in Chicago in 1860 were 25.28 pere 10,000 (276 deaths in 109,206 population). In 1900 they were 15.30 per 10,000 (2,599 deaths in 1,698,575 population), a decrease of nearly 40 per cent. (39.1) of tuberculosis mortality in the 40 years. From pneumonia the 48 deaths in 1860 represent a rate of 4.40 per 10,000 of the population; in 1900 the 3,389 deaths represent a rate of 19.95 per 10,000, an increase of more than 350 per cent. (353.4) of pneumonia mortality. The whole country shows a decrease of 20.7 per cent. of deaths from tuberculosis and an increase of 7.4 per cent. of deaths from pneumonia during the forty years.

What is the cause of this increase of mortality among the patients suffering from pneumonia in our time? Probably one important factor in the increased fatality in the cases of pneumonia occurring in large cities is the class of patients who are treated in city hospitals.

Many of these patients are hard drinkers, and the mortality among such persons is always very large. Another factor that has been dwelt on and has undoubtedly swelled the average of mortality has been the advent of *acute epidemic influenza* (commonly called la grippe). Many other causes might be adduced to explain the failure of our art in curing this disease, and the interesting query comes up whether our change of treatment and abandonment of blood letting has not been a factor in producing this discouraging result.

Let me describe a class of cases of acute pneumonia in which blood letting is not only advisable, but absolutely necessary to save the life of your patient. We will suppose, for instance, the case of a young man in vigorous health, a hearty eater, full blooded and one who perhaps, while not an habitual drinker, yet loves the good things of this life, not wisely, but too well. Such a young man is attacked with acute pneumonia, and in three, four, five or six days perhaps, you will see crape on his door, and are shocked to hear that he is dead. What is the cause of such a young man's death? In the process of inflammation which occurs, perhaps one-third, one-half or even two-thirds of the lung tissue of your patient is filled up with a glutinous lymph which plugs up every air vesicle and thus preventing almost entirely the access of air in all the smaller bronchi. You cut into such a lung in the postmortem room and you find it solid. You drop it into water and it sinks like a piece of liver or other solid organ. Now what is the condition of that man's circulation? The heart, which perhaps beats normally at 65 or 70 is now beating 100, 110, or even 120, 140 or 150 per minute.

Your patient's face and lips are perhaps cyanosed, his respirations are 30, 40 or even 50 per minute. He lies quiet and says but little, for his breath is too precious to be wasted in words, but with imploring eyes he looks to you for help. In such a case bleed such a patient at once and you will probably save his life. What harm can you possibly do to such a patient by bleeding him? The loss of blood is nothing to him, he has too much of that in his body now for his present needs. In other words, here is an inflamed lung the aerating surface of which is diminished to one-half or one-third, or even one-fourth of its normal capacity. At the same time the heart is pumping the blood with greater force and frequency than in health into the semi-solid lung. How does this patient die? Simply because there is not sufficient oxygen brought to the lung to properly purify the impure venous blood and convert it into the life-giving arterial blood. The heart works harder and harder to perform the impossible task assigned to it, but finally gradually fails in power, and death speedily ensues.

Take in a case like this a pint or a pint and a half of blood from the arm and you accomplish two things, first you take away the surplus blood which is overfilling and engorging the blood vessels of the lung, and secondly you diminish the force and frequency of the heart's action, which is sending to the inflamed lung far more venous blood than it can purify.

---

[1] The Journal A. M. A., June 6, 1896, p. 1113.

[2] Charlotte N. C. Medical Journal, September, 1898, p. 299.

The objection may be made that your patient may be unable to spare such a large quntity of blood from the drain thereby made on his vitality; if so the remedy is easy. At the same time that you bleed him, or immediately thereafter, inject by hypodermoclysis under the skin of the thorax or abdomen just the same quantity of normal salt solution (1 to 1,000) as you took from your patient by bleeding.

BLEEDING IN PUERPERAL ECLAMPSIA.

The indisputable facts that puerperal eclampsia occurs most frequently in primipara and in young women in the prime of life would seem to indicate clearly that it must be caused by a toxemia resulting from deficient metabolism and the retention of effete and waste products in the body. What is the cause of this toxemia? How can it be remedied? We are strongly convinced that the cause is a very simple and obvious one, and that this disease is due to the nonassimilation of the large amount of meat and other nitrogenous foods consumed by the majority of pregnant women. After the initial stage of suffering from nausea and vomiting has passed to which many women are subject during the early months of pregnancy, the appetite is apt to become abnormally keen. Patients are encouraged to gratify this abnormal appetite by their friends, and even if the appetite should fail they are urged to eat largely, it being a popular superstition that it is necessary for them to do so in order to nourish properly themselves and their unborn offspring. Another most reprehensible practice is the prescribing by physicians of alcoholic drinks of various kinds at meal times for the purpose of stimulating the flagging appetites of pregnant women. Harm is done by this practice in two ways, first, by stimulating the appetites of these patients, inducing them to partake of more food than they require, and secondly, alcoholic drinks (beer, wine, etc.) diminish the metabolism and encourage the retention of effete matters in the body.

Two other factors entering into the causation of this disease are the neglect to take sufficient exercise in the open air and neglect to keep the skin in healthy condition by frequent bathing and brisk friction.

If the foregoing views are correct and the chief causes of puerperal eclampsia are improper diet and hygiene, the question arises, how can this disease be prevented?

It is my firm conviction, based on 47 years of continuous practice, that many of these cases can be prevented, and, of course, preventive treatment is far more important and more successful than the remedial. The following case is an illustration of preventive treatment;

Mrs. M. R., aged 22, is of healthy physique, and had always had execellent health. She engaged me Dec. 10, 1901, to attend her in her first confinement. She was at this time eight months pregnant. She was to go to Columbia Hospital for Women, which she entered Dec. 31, 1901. She complained of severe and continuous headaches, with sparks of fire before her eyes and some vertigo. Her urine was examined and showed the presence of albumin and tube-casts and a great deficiency in the amount of urea; it averaged only three to four grains per fluid ounce. She was immediately placed upon a rigorous diet, and not allowed to take more than one-third her usual allowance of food. Meat and stimulants were absolutely interdicted, and she was given thin soups and a small amount of milk and farinaceous food. For medication she was given broken doses of calomel, followed by mild saline cathartics so as to secure two or three loose movements of the bowels per day. She was also given a mixture of citrate of potash with a small proportion of potassium bromid. Under this treatment she gradually improved and the amount of urea excreted gradually increased, though it never came up to the normal amount. She was watched carefully, and, greatly to my relief, symptoms of labor set in Jan. 10, 1902. Her confinement and her convalescence were normal and uneventful.

The above preventive treatment, however, has a much wider field in the earlier months of uterogestation. The urine of every pregnant woman should be systematically examined at least once a month until the end of the term.

If albumin is found in the urine (especially if accompanied by deficient excretion of urea) it shows that the elimination of waste material is abnormally lessened; purgatives and diuretics should be given. Hydrotherapy with diminution of or total abstinence from nitrogenous food and alcohol, are also powerful adjuncts in the treatment of these patients.

But there may not be any opportunity for preventive treatment, for the patient may be already in a state of coma or in the throes of puerperal convulsions when we first see her. This is an emergency that will tax to the utmost the skill and self-reliance of the most accomplished physician. What shall we do? Shall we proceed to empty the uterus, bleed, give inhalations of chloroform or use morphia? In regard to the first treatment mentioned all authorities practically agree that if the convulsions develop during the labor, at full term, delivery should be accomplished either by version, the application of the forceps or other means as rapidly as possible. This rapid delivery of the child will very often arrest the convulsions, or if it does not do so entirely, will so mitigate them as to render the case comparatively easy of treatment.

This is not invariably the case, however, for one of the severest cases of puerperal eclampsia ever met in my experience was one in which the convulsions began after the labor had terminated satisfactorily. The labor had not been unusually severe for a primipara, but there was a smaller flow of blood from the uterus during and after the labor than is usual. The patient was a vigorous healthy woman, plethoric and with full tense pulse. The convulsions continued for 24 hours subsequent to the termination of labor, in spite of the free use of inhalations of chloroform, and the administration of chloral and morphia combined with bromids. The attending physician and myself, becoming almost desperate, finally determined to bleed her. By the dim light of a candle we bled her from the arm to the amount of 20 ounces, and there was almost instantaneous relief. The convulsions stopped at once and she made an uneventful recovery. We felt satisfied from the full and hard character of her pulse that the convulsions were continued by the blood pressure on the cerebral centers, and the result seemed to confirm this view of the case.

No one at the present day would wish to revive the old Sangrado system of indiscriminate bleeding for every disease, but it is the firm conviction of many physicians, of whom I am one, that we have been too hasty in abandoning the use of blood letting. The field of usefulness of bleeding, however, is very limited, and it is only in such cases as the one just described that we would recommend it.

That Annual Bath.—To illustrate the rôle that personal uncleanliness plays in disease among the lower classes, *American Medicine* tells the story of a mother who sought the aid of a physician for her sick child. A physical examination being necessary, the physician attempted to remove some of the child's clothing, but became lost and asked the mother to undress the child. She replied, "Aber, mein Gott, I have sewed it in for de Vinter."

A DIAGNOSTIC EXAMINATION OF ONE HUNDRED AND FIFTY CASES OF LEPROSY.

JONATHAN T. McDONALD, A.M., M.D.
Pathologist to the Hawaiian Territorial Board of Health; Secretary Hawaiian Territorial Medical Society; Consulting Physician to the Queen's Hospital, Etc.
HONOLULU.

Leprosy is a disease to which the average American physician gives but little thought or study; he is accustomed to regard it as a foreign malady, of interest to him only as a curiosity. This is a mistake; leprosy has existed for many years in various parts of the United States, but the only recognition it has thus far received has for the most part been by dermatologists in the centers of population.

The ordinary general practitioner, "the backbone of the profession," and to whom this paper is presented, is the man on whom rests the responsibility of keeping in mind the general features of the disease, and the possibility of some day encountering a case when least expected, as it is essentially a constitutional disease as much as is tuberculosis, and comes as fairly within his own domain.

With us in Hawaii the disease is on the decline; thus proving the wisdom of the policy of segregation established over thirty years ago. Our method of apprehending and dealing with leper suspects may be stated briefly as follows: The entire inhabited portion of the territory is divided into twenty-six government districts, in each of which a competent, resident practitioner is selected and appointed by the Territorial Board of Health as government physician, with a small annual salary. In conjunction with his private practice he is to treat the indigent sick free of charge, supervise sanitation and vital statistics, return monthly reports on health conditions in his district, etc., and last, but not least, he is to be on the constant, vigilant outlook for lepers. In this latter duty there is placed at his disposal the active co-operation of the district deputy sheriff, who in many instances is the one who discovers the suspect and brings him to the attention of the physician. From these two officials, whose powers and duties in the matter are not optional, but mandatory, come most of the recruits for Molokai. A few of the patients, hidden away for years by friends, are already well advanced in the disease, but very many and perhaps the majority would "pass in a crowd" unnoticed. These are the ones whom the government physician has held under suspicion and silent observation perhaps for months, or even years, to study the progress and development of some slight and uncertain lesion regarded as of no importance by the patient himself, or perhaps by him entirely undiscovered.

Arriving at Honolulu, the suspect is placed in the leper receiving station, an enclosure of several acres containing cottages, wards, dispensary, etc., and situated in a quiet suburb some three or four miles from the business center of the city. He now passes under the care of the pathologist of the Territorial Board of Health, whose duty it is to supplement the work already begun by the government physician, in formulating the history of the case, making a critical study of all symptoms, recording the *status præsens* and demonstrating if possible the presence of the bacillus lepræ. After the arrivals have amounted to about twenty, the official examining board is called together in session at the station to make a final individual review of each case and pass on its disposition.

The following observations are based on an examination of a series of one hundred and fifty cases, mostly native Hawaiians, collected within the past two years and sent to Molokai; the diagnosis in each and every case having been either made or confirmed by a bacteriologic demonstration.

As a means of diagnosis first in importance stands the microscope. Although not regularly and scientifically demonstrated, on account of the universal failure both to obtain a pure culture and to infect any lower animal, yet it is now generally accepted the world over, that the disease is due to the Hansen bacillus, precisely as tuberculosis is due to its own specific germ. The discovery of the *Bacillus lepræ* in suspicious tissue is now considered just as legitimate diagnosis of leprosy as is that of the tubercular bacillus in the sputum of a suspected consumptive, confirmatory of tuberculosis.

The method employed is essentially that of my fellow townsman, Dr. L. F. Alvarez, described by him before the Berlin Leper Congress in 1897. A minute test snip of the suspected tissue is thoroughly triturated in a small mortar with a few drops of normal salt solution; a drop or two of this is placed on a cover glass, dried, fixed and stained with Ziehl's carbol fuchsin in precisely the same manner as with tubercular sputum, bearing in mind the single fact that the *B. lepræ* both takes and gives up its stain more readily than the *B. tuberculosis*, hence, in decolorizing, a very weak acid must be employed. Finally, contrast stain, mount and examine with a one-twelfth oil immersion and a good light. Slides thus made from snips of typical nodules usually show the bacilli in incredible numbers, or rather quantities, as I have frequently observed more than half the field occupied by the bright red aggregations of cell masses, great irregular blotches of solid bacilli in myriads, with small groups and individual elements intervening.

But, as has already been intimated, not all of the cases coming to the station show typical nodules. The majority present, it is true, in greater or less degree, one or more of the symptoms enumerated below, but frequently of so slight a nature as to render a positive diagnosis impossible without the aid of the microscope. In these cases we have to select our test snip from some locality on a given subject where experience has taught us we shall be most likely to find the bacillus. It may be that the best we have is an area no larger than a dime on arm, neck, back or thigh, which shows only a loss of pigment so faint as to be seen only in a favorable light. Slides made from here show a sorry contrast to the ones mentioned above which present a demonstration at first glance. We now anticipate a long and tedious search. With the mechanical stage we go back and forth, to and fro, by the half hour. Not that a leucodermic spot or two is of such grave import, as it is not; but the patient has also, it may be, an open sore on the bottom of his foot which he gravely tells you is from a cut on a sharp shell received a month or two ago while fishing, or there may be a slight atrophy in the palm of one hand; he is under suspicion. This impels one to presevere, when, perchance, one lonely red rod comes into the field; later two side by side; another long search and another single individual; and finally perhaps a group of from twenty to fifty; the diagnosis is no longer in doubt.

Writers of leprosy literature tell us that open ulcers and their discharges are teeming with bacilli; in this I have been greatly disappointed. Take, for instance, the common plantar pedis ulcer perhaps as large as a half dollar and a half a centimeter in depth. I have so many times obtained negative results in smears from discharges or scrapings from its base that I have wellnigh abandoned their bacteriologic consideration. Another disappointment has been the mucus from the cartilaginous portion of the nasal septum. Even so high an authority as Koch has declared that the bacillus is to be found here early and constantly. After many faithful trials in every stage of the disease I have found them so seldom that I now attach but little importance to it as a means of diagnosis.

While the microscope is thus first in importance, it is in practice the last agent to be employed; it is only after all the various symptoms have been canvassed that an appeal to it is made as a court of last resort. What are the chief clinical features whose existence place the subject under suspicion? An attempt will now be made to present the more important ones in the order of frequency as we have found them in our series of cases.

The ancient division of leprosy into tubercular and anesthetic is unfortunate, as to terminology at least. The former, although used, of course, in its dermatologic sense, has long since been wholly appropriated by another entirely distinct disease, and its use in connection with leprosy ought to be abandoned. The latter term also is inapt, as in many well-marked cases of its type anesthesia is not a predominating symptom. There is but one leprosy; it shows in its manifestations a predilection for the skin and the nerves; that is all there is to the "three types, viz., tubercular, anesthetic and mixed" of authors.

First, then, in point of frequency, comes the symptom or rather group of symptoms which, for convenience, we class as maculæ, occurring in 89 per cent. of all our cases. Of these by far the most common are the leucodermic spots or areas which occur in all sizes and in all regions. They seem absolutely healthy to touch and feel; no elevation, no thickening, no inflammation; they seem to have lost a little of their pigment and that is all, unless, as rarely happens, they may be somewhat anesthetic. The patient, as a rule, knows but little of their origin or length of existence. A recent willing patient, an intelligent Hawaiian woman, a leper, anxious to go to Molokai to join her husband and her brother, detailed to me the symptoms of an erythema which occurred some four years ago with chilliness, slight fever and malaise; after these transitory symptoms had passed, the areas occupied by the redness, gradually and permanently lost a little of their pigment. It seems quite probable that such is the usual origin of the leucodermic spot. Taken in connection with other symptoms these spots and areas constitute a strong presumptive and confirmatory sign; taken alone, however, they are of very much less significance.

To the other and rarer lesions grouped as maculæ even less importance is to be attached. They all belong to the array of indefinite "might-be's" daily encountered in every skin clinic, suggesting syphilis, eczema or other ordinary dermatoses and not exclusively characteristic of leprosy. Repeated test snips with negative results have convinced me that, as a diagnostic sign, they are of much less value than is the leucodermic spot.

Next in frequency come the so-called tubercular lesions, the pathognomonic sign of skin leprosy. Under this head we group all patients who show the least trace of the true leprous nodule however slight, and our records show that it was found in 111 cases, or 74 per cent. In many of these it was so slight as to readily escape notice without careful search.

The histologic character of the lepra nodule in and beneath the skin is very suggestive of granulation tissue; in fact, Virchow coined a term, granuloma, to express it; the growth consists of proliferated connective tissue cells and leucocytes, with fibrous intercellular formations and newly formed capillary blood vessels. Ordinarily the nodule varies in size from that of a half pea to half a walnut, but it may be as small as a pin's head, or, on the other hand, of several inches in extent; it is irregularly circular or oval in shape, quite definitely circumscribed, with a well-rounded elevation, not particularly hard or resistant to feel, and in the lighter-skinned races with a tendency to brownish or coppery pigmentation. Its favorite region is the face, with a strong attraction for the lobule of the ear. I can not confirm the statement of authors who mention the elbows as a usual site; I have rarely found nodules in that region. Next to the face, the trunk may show them; less often the limbs. Instead of the nodule there is frequently found, as in the cheeks, for instance, quite an area of subcutaneous thickening, with perhaps slight elevation, the skin smooth, rather hard and firm to the touch, as though there were just beneath it a layer of thin leather. This is believed to be of the same nature as the typical nodule, differing from it only in manner of disposition. The facial disfigurements with the classic leonine expression pictured in the books as typical leprosy are nowadays seldom seen at the receiving station, but are more common at Molokai.

Another symptom of value is the falling of the eyebrows and lashes. Including all patients in which it appeared in any degree the records show 94 cases, or 63 per cent. While many of these presented but a thinning of the eyebrows in the outer half, those recorded as "entirely gone" and "nearly gone" number 31. It seems to be an idiosyncrasy of the disease, occurring without any appreciable change in the skin from which the hairs fall. In this connection it may be remarked that the disease has an apparent aversion to the hairy scalp, as I have not seen a single case thus affected.

We now come to an important group of symptoms more directly indicative of trophoneurotic leprosy as seen in atrophy of the palm and forearm with resultant retraction of the first row of phalanges, combined with contraction of the remaining phalanges, constituting the well-named "leper claw." Like all other symptoms, this one exists in every degree of severity. It may be so slight that the patient himself has not noticed that one palm is thinner than the other; or, in another case, while he is unable to entirely straighten two or three of his fingers, he has not observed that the forearm is somewhat smaller than its fellow of the other side. This group of symptoms constitutes 32 per cent. of all cases. Its usual manifestation, fortunately, is on one side only, but it is not rare to see both hands affected and to a marked degree, reducing the patient to the pitiable condition of almost total helplessness. In all these cases the ulnar nerve above the inner condyle will be felt enlarged and firm as a cord under the examining finger.

Next in order stands the plantar ulcer with a record of 26 per cent. Of variable size and depth, usually single, but sometimes multiple, it occurs most frequently on the ball of the foot, but also on the heel, and I have found it even on the bottom of a toe. As a clinical symptom it must be regarded as of great diagnostic value, as the lesion is very distinctive in its fully developed state and would hardly be produced in any other way. It might be of interest, in passing, to state that with the enforced rest, the generous diet and local treatment, many of them entirely heal in a few weeks' stay at the station.

The text-books have brought into undue prominence the spontaneous amputation of fingers and toes from absorption of phalanges. It is not so common as is generally believed. We have grouped all cases which have shown even a tendency to this condition, as in the slight shortening of a phalanx, together with the very few in whom we have found parts of fingers or toes entirely gone, and our records show that these cases amount to only 16 per cent. of all patients. I recall but one case in which we found a tolerably healthy looking toe hanging by a short fibrous pedicle about three millimeters in diameter. Hence, while the symptom is a very characteristic and valuable one, it is not very common.

Occurring with the same frequency as the above, in 16 per cent. of all cases, is a condition of the hands and sometimes of the feet, recalling an old classic name of leprosy, *elephantiasis Græcorum.* Instead of atrophies and contractions, we now find the wrists, hands and fingers more or less enlarged, rather soft and flabby, with the skin smooth and always of a dusky purplish tint. Except the color, it suggests at first glance a well-marked edema, but lacks, on palpation, the tense or boggy feel of that condition. Another interesting point is that the fingers invariably gradually taper toward their ends, so that about the nails their size is entirely normal. Test snips from several of these enlarged hands and feet have failed to show the bacillus.

Another symptom of trophoneurotic leprosy is facial paralysis, which we found in 11 per cent. of our series, in nearly all of which the side of the face was entirely motionless and expressionless with the orbicularis palpebrarum greatly deficient in function.

Finally, as to the universally recognized symptom of anesthesia. I have frequently found large anesthetic areas of skin to all outward appearance entirely normal; while, on the other hand, I have as often found areas which we would suppose should be anesthetic, with sensibility unimpaired. With us its determination is attended with difficulties and uncertainties. Nearly all our cases are unwilling, unsympathetic patients. Many are overcome by fear and are as profoundly startled by the touch of the head of a pin as by a prick of its point, while the answers "Ae" and "Aole" (yes and no) are given with utter lack of thought, care or discrimination. It is certainly one of the most valuable symptoms, and is probably as frequent a one as authors have claimed it to be. Our own statistics on this point are so meager and worthless as to preclude mention.

These few objective symptoms, while by no means complete, comprise the leading characteristics of leprosy, constituting an efficient aid to its recognition. The more so in that in every leprous case we have a combination of two or more symptoms, and often as many as five or six of them illustrated on the same patient. Thus, we might have leucodermic macules here and there on the trunk, the eyebrows thinned, a palm slightly shrunken, an enlarged and tender ulnar nerve, anesthetic areas, and a shortened toe all in the same patient, who would even then not only fail to attract the attention of his associates, but might consider himself in very good health.

A brief summary of the above may be deduced as follows:

1. The microscope is the supreme agent of the final diagnosis of leprosy. No patient should be committed to a segregated colony without a bacteriologic demonstration of the disease.
2. Of clinical symptoms, maculæ, chiefly leucodermic spots are found in 89 per cent. of all cases.
3. The lepra nodule found in 74 per cent. is the one chief distinguishing lesion of skin leprosy.
4. Thinning or complete loss of eyebrows and lashes is present in 63 per cent.
5. Atrophic changes in hands and forearms with retraction and contraction of fingers and enlarged ulnar nerve in 32 per cent., a leading feature of nerve leprosy.
6. The plantar ulcer found in 26 per cent., usually on the ball of the foot.
7. Absorption of phalanges in 16 per cent., with occasional spontaneous amputation.
8. Elephantiasis of hands and feet in 16 per cent.
9. Facial paralysis in 11 per cent.
10. The entire body should be carefully tested for anesthetic areas.
11. Several of the above symptoms can be found in some slight degree at least in every leprous subject.

THE CHEMISTRY OF CEREBROSPINAL FLUIDS.

TORALD SOLLMANN, M.D.
From the Pharmacologic Laboratory of Western Reserve University.
CLEVELAND, OHIO.

During the last few years I have examined a number of cerebrospinal fluids from lumbar punctures. The analyses are of some interest, as they throw light on such disputed questions as the molecular concentration and the nature of the proteids. In other respects they may serve to enlarge somewhat the already existing knowledge of this fluid. The specimens were usually not analyzed until a day or two after they were drawn, but they were received and preserved in sterile flasks, kept very cold. The first four cases were furnished by Dr. C. J. Aldrich, from patients with febrile temperatures. The last fluid was given me by Dr. C. E. Briggs. I wish to take this opportunity of thanking these gentlemen for the material.

SUMMARY OF ANALYSES.

The results of the analyses are briefly as follows:

APPEARANCE.—Fluids I to IV, are perfectly clear and colorless, III containing a very small sediment; V (from a case of spina-bifida) is slightly pinkish from suspended blood, the corpuscles having a perfect outline. They soon subside and are removed by filtration. The fluid is clear and colorless II contained a delicate whitish membrane, which dissolved, for the most part, in 0.4 per cent. HCl.

SPECIFIC GRAVITY (taken with picnometer).—II = 1.0137; III = 1.0091; V = 1.0079.

REACTION.—Slightly alkaline in all cases.

DEPRESSION OF FREEZING POINT.—III = 0.541° C; IV = 0.535; V = 0.591.

COMPOSITION.—Total solids: III = 9.60 0/00; V = 13.25 0/00 Ash: III = 7.23 0/00; chlorids (as NaCl): III = 5.73 0/00; V = 6.0 0/00. Non-proteid organic matter (by difference): III = 1.64 0/00. Non-coagulable proteid: None in III or V. Coagulable proteid: I = 0.525 0/00; II = 1.16 0/00, globulins present; III = 0.726 0/00 globulin, no albumin present; V = 2.57 0/00 globulin, no albumin present. Reducing substance: Present in I and III (in III less than 0.3 0/00); absent in II (polarimeter, Moore's phenylhydrazin, Trommer's and fermentation tests).

COMPILATION OF ANALYSES.

I have searched through the literature (see bibliography) for other analyses and found about 30 recorded of human cerebrospinal fluid, and a somewhat larger number for other mammals. Adding to these the fluids analyzed by me, I have compiled the following table, which, I think, gives a sufficient picture of the chemical data of this fluid.

	Specific Gravity.	Depression of Freezing Point.	Total Solids. Per cent.	Total Ash. Per cent.	Coagulable Proteid. Per cent.	Reducing Substance. Per cent.	Clorin as NaCl. Per cent.	Urea. Per cent.
Human.

DISCUSSION OF THE RESULTS.

Physical Factors.—The molecular concentration as determined by Beckmann's method was, in three of my specimens, that of normal serum. This result differs from that obtained by Zanier with Hamburger's blood corpuscle method. According to Zanier the cerebrospinal fluid of the ox is hyperisotonic to the blood serum. One c.c. of the fluid required the addition of 1.3 to 1.35 c.c. of water to produce laking, whilst serum required only 1.1 c.c. It must be remembered in this connection that Hamburger's method is only applicable when the solution to be investigated contains no molecules which can enter the corpuscles. I compared the results of this method with the freezing point in fluids IV and V. In Case 4 5 c.c. of the fluid required 4 c.c. of water to lake rabbit's blood (being therefore isotonic with a 1.1 per cent. solution of NaCl); 5 c.c. of fluid V required between 3.0 and 3.5 c.c. of water to lake human blood (isotonic with 0.98 per cent. NaCl). The determinations were made rather roughly and no comparison with serum was possible. Comparing them, however, with the depression of freezing point (IV, 0.535; V, 0.591) it is seen that the two methods do not yield analogous results. It would seem, further, that something in the cerebrospinal fluid protects the corpuscles against laking. In view of these results, Zanier's experiments need verification by the simultaneous employment of Beckmann's and Hamburger's methods.

The specific gravity varies within narrow limits for all animals and is always lower than that of serum, on account of the small proteid content. The reaction is always slightly alkaline. (According to E. Cavazzani the specific gravity and the alkalinity are somewhat greater in the morning than in the evening.)

The inorganic salts exist in about the same amount as in the serum, and consist mainly of chlorid. The average per cent. of this salt is that of serum. Foreign salts can pass from the circulation into the cerebrospinal fluid, as shown by A. and E. Cavazzani, for potassic iodid and ferrocyanid. This passage is, however, much slower than the excretion into other fluids. The salts can not be detected in the cerebrospinal fluid until after an hour, whilst they appear in a few minutes in the aqueous humor. When salts are injected into the subarachnoid space, their absorption is also very slow, requiring from 20 minutes to two hours. I had opportunity to convince myself of the presence of iodid in the cerebrospinal fluid of a child treated with KI.

Reducing Substance.—The constant occurrence and the nature of the reducing substance of cerebrospinal fluid was long a matter of discussion. Halliburton claimed that it did not reduce bismuth, and that it was pyrocatechin. These statements did not pass unchallenged. Nawrotzki, who gives also the literature of the subject, has finally settled the dispute. He finds no pyrocatechin, and shows that the substance gives all the tests of dextrose. This sugar is present in every freshly drawn specimen of the fluid, but disappears on standing. The statement of Comba, that it is always absent in meningitis lacks confirmation. Its absence in my fluid II is easily explained by the time which elapsed between the puncture and the examination.

Coagulable Proteid.—Halliburton ascertained that this is completely precipitated by $MgSO_4$, and is therefore globulin. The absence of albumin was also confirmed in the case of Thomson, Hill and Halliburton. It was also absent in the two fluids (III and IV) in which I tested for it. This normal absence of albumin in a fluid containing globulin is apparently a unique phenomenon. Panzer claims to have found albumin. It is possible that the presence of this proteid could be due to an admixture of inflammatory exudate, and that it might have a diagnostic value. Further observations are very desirable. The quantity of the proteid varies between rather wide limits, but 17/20 of the analyses show less than 2 per cent. Nawrotzki claims that a high per cent. of proteid is connected with fever. This claim needs further support. Halliburton affirmed the presence of a non-coagulable proteid. This has not been found by other investigators, and none was present in the fluids III and V in which I sought for it. Halliburton's results probably rested on an error of technic. The same author claims that fibrinogen is absent. The membrane in fluid II appears to show that fibrin may be formed, although the quantity of material did not permit positive identification.

Diastatic Ferment.—This may be present, although in less amount than in lymph or serum (E. Cavazzani). Panzer found none. Cavazzani also found an oxidizing ferment, which blues guaiac before boiling. Thomson, Hill and Halliburton found no cholin in their case.

CLINICAL OBSERVATIONS IN STOMACH SURGERY.*

A. J. OCHSNER, B.S., F.R.M.S., M.D.
Surgeon-in-Chief of Augustana Hospital and St. Mary's Hospital; Professor of Clinical Surgery in the Medical Department of the University of Illinois.
CHICAGO.

Surgery of the stomach is still in a developmental state. Many surgeons are making progress in this field, and although there can not as yet be many conclusions which can reasonably be expected to be permanent, still it seems worth the effort to exchange the points of clinical experience at this time.

It is, of course, out of the question to discuss this subject thoroughly in the time given to a paper in this Section, but I believe that it will be possible to present the features which seem of greatest practical importance as they have impressed themselves on me in my clinical observations.

Ultimately the greatest portion of stomach surgery must be done for the relief of gastric ulcer or one of its various sequelæ—hemorrhage, perforation, adhesions, cicatricial contraction with pyloric obstruction and its consequent gastric dilatation, hour-glass stomach and carcinoma. The wider my field of observation has become the more I am convinced that there is in this condition a great opportunity for surgical work of the highest value.

The operation for the relief of hemorrhage from a gastric ulcer, introduced by Mikulicz sixteen years ago, which has been practiced by many surgeons, but was brought to the general attention of the surgical profession especially by the clearness and force of Mayo Robson's writings, will become less and less indicated as the practitioners of internal medicine become convinced of the fact that these cases can be safely relieved by a simple operation performed in the interval between attacks.

The same condition will reduce the frequency with which the surgeon will be called on to operate for the relief of perforative gastric ulcer. The statistics of Wier and Foote and those of Tinker will serve to indicate the gravity of this operation, especially when compared with the statistics of Mayo, Finney and others, of operations performed in the interval.

In all cases of ulcer of the stomach which do not heal completely and permanently by internal treatment or in which the healing is followed by pyloric obstruction, it seems proper that surgical treatment be employed. There are three factors which aid greatly in bringing about this conclusion: 1. The diagnosis can now usually be made without difficulty because the attention of the profession has been sufficiently directed toward this condition to make its recognition probable. 2. The operative technic has been so thoroughly perfected that interval operations are accompanied by very little danger. 3. A sufficient number of cases have been observed for a number of years to make the permanency of cure an established fact.

Mayo established the principle of providing perfect drainage of the deformed stomach by making an anastomosis between the very lowest portion of this organ with the jejunum. This is the most important factor which has served to build up a satisfactory technic in this class of cases. Many surgeons operating on the stomach have not yet grasped this idea. This is true especially of the surgeons who have been unsuccessful in this class of work. It should be stated here that in making a posterior gastroenterostomy the surgeon will employ this principle in most cases, whether he does it intentionally or accidentally, but in the anterior operation he is just as certain not to do this, unless his attention is fixed on this end at the time of the operation.

In my own experience the persistent vomiting after gastroenterostomy—"vicious circle"—has been absent since I appreciated this principle and have applied it. The vomiting simply resulted from the fact that fluid could not help flowing into the stomach from the proximal end of the small intestine, because it had to flow down hill, the opening in the stomach not being in the lowest point of this organ. All that has been said and written concerning the cause of this pernicious vomiting, with the exception of what refers to this one condition, is, I believe, based on faulty observation, and all of the complicated operations which have been invented to prevent this vomiting are unnecessary, if the principle introduced by Mayo is properly appreciated and applied.

ELASTIC LIGATURE METHOD.

It is probably of little importance whether the anastomosis is made with ordinary sutures or with those aided by a mechanical splint, like the Mayo-Robson decalcified bone bobbin, or with the Murphy button. In all but thirteen of my cases I have used the Murphy button, in four the needle and thread and in nine the McGraw elastic ligature. All of the latter I have made during the present year, and have found the method exceedingly easy and satisfactory so far as the immediate results are concerned. None of the patients showed any shock. They were all able to sit up in bed on the day following the operation and all recovered. The time which has elapsed since these operations were performed is, however, too short to determine the ultimate result. The points of importance in this method are that as large an opening as desired can be obtained and that there can not possibly be either separation or leakage or infection from the intestinal or stomach contents.

In applying the method the following conditions must be borne in mind: 1. A round rubber cord 2 mm. in diameter, made of the best material, should be used. 2. A posterior row of Lembert sutures is applied. 3. A long, straight needle armed with the rubber ligature is passed into the lumen of the intestine and out again at the desired distance, from 5 to 10 c.m. away from the point of introduction. 4. While an assistant holds the intestine the surgeon stretches the rubber in the needle and when quite thin draws it rapidly through the intestine. 5. The same step is repeated through the stomach. 6. A strong silk ligature is placed across and underneath the rubber ligature between the latter and the point where the stomach and intestine come together. 7. A single tie is made in the rubber ligature after the latter has been drawn very tightly. 8. The silk ligature is passed around the ends of the rubber ligature where they cross and tied securely three times. 9. The ends of the latter are released and cut off, being held by the silk ligature. 10. The Lembert suture is continued around in front until the point of its beginning is reached, where it will be tied. 11. Care must be exercised to prevent tying the rubber ligature too far backward and thus getting behind the posterior row of Lembert sutures.

I am thus explicit in describing the steps of this operation because I find that only those who are thoroughly familiar with the method have used it, and apparently all with great satisfaction.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

It has been found that a gastroenterostomy opening made with a Murphy button will remain open and act perfectly in cases in which the pylorus is permanently occluded, but in cases in which it is only temporarily occluded because of an open ulcer with its resulting induration and edema, the gastroenterostomy opening contracts as soon as the pylorus again becomes normal or nearly so. Unfortunately, this closure of the gastroenterostomy opening is likely to be followed by a recurrence of the ulcer and the consequent obstruction of this orifice, which frequently necessitates a repetition of the operation.

This can be avoided by making an excision of the pylorus at the time of the primary operation or by closing the pylorus with a silver wire passed around the pyloric end of the stomach or the beginning of the duodenum two or three times, drawing it just tightly enough to occlude this orifice completely, but not sufficiently tight to cause pressure necrosis. This method has, however, not been tried sufficiently to secure its absolute establishment.

It is claimed that by making a large anastomotic opening by means of the McGraw elastic ligature one can secure a permanent opening under all conditions. My own cases are still too recent to be of value in confirming this claim. The results secured in cases of the class under consideration by the operation of gastroenterostomy properly performed are certainly very encouraging.

Recently Fowler has described an operation consisting in gastroenterostomy and enteroenterostomy between the portions of the jejunum at the proximal and distal side of the point at which the anastomosis was made with the stomach. Aside from this the intestine is occluded by means of a silver wire passed three times around its lumen between the point at which it is anastomosed with jejunum and the stomach, so that the bile and pancreatic fluid can be emptied into the small intestine, but not into the stomach. This operation has given very satisfactory results in the hands of its author, but in my experience the much simpler method of making an anastomosis between the lowest portion of the stomach and the jejunum has been so satisfactory that I have not found it necessary to make the more complicated operation.

PYLOROPLASTY.

Operations for the enlargement of a contracted pylorus have not been very satisfactory, principally because the obstruction was not fully relieved by the operation usually employed—the Heinecke-Mikulicz or some modification of this—on account of the pouch-like deformity which is present in most of these cases, necessitating the elevation of the food to the level of the pylorus before it can be emptied into the duodenum even after the plastic operation has been made on the contracted pylorus.

One year ago Finney published a method which seems to promise well, but it has not attained sufficient age to have stood the practical test of time. I have employed this method but once, making use of the McGraw elastic ligature instead of making the horse-shoe shaped incision.

Theoretically this is a good operation and practically it can be performed with great ease. It will be interesting to observe the permanent results in the cases which have been operated on by this method during the past year.

In many cases a very moderate pyloric obstruction will give rise to most distressing symptoms because it is accompanied not only with a pouch-like deformity of the greater curvature of the stomach, but because at the same time gastroptosis is present. Thus the normal drainage of the stomach is interfered with mechanically in three ways: 1. By the constriction of the pylorus. 2. By the deformity. 3. By the malposition of the organ.

In simple enteroptosis a number of authors claim great benefit to the patient from various operations intended to elevate the organ. Most of these methods interfere seriously with the mobility of the organ and are painful, for a time at least.

This is not the case with the method described and practiced by Beyea, and that devised independently by Bier. These methods are very similar and virtually consist in shortening the gastrohepatic and gastrophrenic ligaments by means of several rows of fine silk sutures.

Experience seems to show that this method gives permanent relief in simple gastroptosis, the pain disappearing quickly and permanently, and the patient gaining rapidly in weight and strength. Whether this method is applicable to cases such as I have described remains to be seen by experience.

I have operated on but two of these cases by a method similar to those mentioned above, but which at the same time fixed the stomach to the abdominal wall. The results were so unsatisfactory, although in each case I could note some improvement, that I did not repeat the operation.

Since studying the methods described by Beyea and Bier, it seems plain that the interference with the mobility of the stomach prevented the complete recovery of my patients, and that with better technic the results would have been better.

OBSTRUCTION OF PYLORUS DUE TO CARCINOMA.

In carcinoma of the pylorus there is never any indication for performing a complicated operation similar to that described by Fowler in connection with gastroenterostomy, because the pylorus is permanently obstructed at the time of the operation, and this obstruction becomes more complete as time progresses.

In cases in which the tumor is sufficiently circumscribed to make its removal practicable, there is again no occasion for performing any operation except an anastomosis between the remnant of the stomach and the jejunum. It is, however, important to select a point sufficiently distant from the point at which the duodenum passes through the mesocolon to avoid all tension. The operation is very simple if performed after a definite plan.

The duodenum is clamped double after tearing a small opening through the folds of the omenta above and below. It is then severed between these clamps. A circular silk suture is applied to the end of the duodenum, and while this is tied the crushed end is inverted into the lumen of the intestine. A few sutures will serve to cover this circular purse-string suture and complete the closure of the intestine. Then the greater and lesser omentum are caught successively, always between two pairs of forceps, care being taken not to injure the pancreas behind the duodenum to the right and the vessels supplying the colon below.

In this manner any desired portion of the stomach or the entire organ can be removed without causing any considerable amount of shock or the loss of much blood. When a safe point has been reached beyond the growth, two pairs of clamp forceps are again applied and the same steps repeated that were described in connection with the duodenum. Instead of applying a purse-string suture, however, it is best to apply a simple glover's stitch, grasping the stomach wall to either side of the clamp forceps, and passing loosely across the latter. When the entire row of sutures has been applied, the forceps are loosened and the suture drawn tightly. This serves to insert the crushed end of the stomach into its lumen. Then a second row of continuous Lembert sutures is applied over this row, leaving the stomach in the form of a closed sac. An anastomosis is now made between the remaining portion of the stomach and the duodenum, preferably by means of the Murphy button. At this point it is of the greatest importance, first, to choose the lowest point of the stomach; second, to select a portion of the jejunum which is sufficiently free to prevent all tension.

Of course, in cases in which it is not possible to remove the entire tumor, it is much better for the patient if only a gastroenterostomy is made to give temporary relief from the pyloric obstruction.

It should be stated here that occasionally a carcinoma will be found which is apparently perfectly movable, but which is found later to have invaded the pancreas, the latter organ being attached to and moving with the stomach.

GASTRECTOMY.

Complete gastrectomy, although it is now a recognized operation, must always remain rare, because cases in which the disease is sufficiently advanced to require this operation are usually so far advanced that the operation is useless. When indicated, the steps which have just been described are simply to be carried further until the entire organ has been removed. Here again, it is of the utmost importance to unite the esophagus to a loop of the jejunum, sufficiently loose to prevent tension.

I have never removed the entire stomach, but in two cases of partial gastrectomy so small a portion of the cardiac end of the stomach could be preserved that I virtually had an opportunity to test this method. It is very simple, and I believe it must be ordinarily, at least temporarily, successful in cases in which it would be indicated.

In all of these operations there are a few points of great practical value, concerning the preparation of the patient and the after-treatment, which are not generally appreciated and which are consequently worthy of mention in this paper.

Many of these patients entered the hospital in an extremely emaciated condition, because almost always milk is the only food which has been given for a considerable period of time. The stomach contains a quantity of residual decomposing material and the milk which is taken is at once changed into a similar decaying substance, from which it is, of course, impossible to secure any nutrition, even from the portion which may pass the pyloric obstruction into the intestine. If the stomach is carefully irrigated with warm normal salt solution through a large-sized stomach tube before food is given, every three to six hours, the conditions for obtaining some benefit from the food will be greatly improved. In most cases the use of an ounce of one of the various concentrated liquid predigested foods in the market, given in three ounces of normal salt solution after making gastric lavage every three to six hours, will be followed by rapid improvement in strength. In this manner the absorption from the stomach of products of decomposition will be prevented, and for this the absorption of at least a small amount of concentrated food will be substituted. It is best at first to spray the pharynx with a 4 per cent. solution of cocain and to permit the patient to swallow a little of this rather than to wait for five minutes before introducing the stomach tube. This will prevent unnecessary gagging and discomfort of the patient.

It is well to introduce through the stomach tube into the stomach once a day, or less frequently, after the lavage, two ounces of castor oil or olive oil and then to withdraw the tube. Unless the pylorus has been entirely occluded the oil will find its way into the intestine and will aid the nutrition of the patient.

It is well to place these patients on nutrient enemata at the same time. One ounce of one of the liquid predigested foods in the market, dissolved in three ounces of normal salt solution and introduced through a soft rubber catheter which has been inserted a distance of two to three inches, seems to be of the greatest value.

In case the patient is nauseated after the operation, gastric lavage should again be employed at once. If the patient has been accustomed to the use of the stomach tube before the operation, it is, of course, a great advantage to him after the operation.

It is important to use only a small amount of water in making gastric lavage after the operation for fear of disturbing the healing of the wound in the stomach. We introduce but half a pint at a time. Neglecting this precaution caused the death of one of my patients.

Rectal feeding should be continued for two weeks after the operation, but small amounts of predigested liquid nourishment may be given every three hours by mouth after the fourth or fifth day in most cases.

I have reviewed the histories of the cases on which I have made stomach operations at the Augustana Hospital, and find that in seven cases gastrostomies were made for the relief of obstruction of the esophagus; one of these was made for the purpose of dilating a benign stricture, one for the purpose of feeding a patient who had been starved to a mere skeleton because of the presence of a diverticulum which had completely occluded the esophagus. The former case recovered, the latter died of exhaustion. She was in an almost hopeless condition when she entered the hospital. Of the five remaining cases operated on for obstruction of the esophagus due to carcinoma, three recovered and two died of exhaustion, being in a hopelessly starved condition when admitted.

Two cases operated on for perforation of the stomach, one due to ulcer, the other due to gunshot wound, both died from diffuse peritonitis which was present at the time of admission. In each case the perforation had existed for eighteen hours and the abdominal cavity was full of food and a thin cloudy fluid.

There were nine pylorectomies and incomplete gastrectomies with three deaths, one from shock two hours after the operation, one from overdistension of the small remnant of the stomach with fluid during gastric lavage after the patient had been normal for four days. The lavage was ordered because the patient was slightly nauseated and the nurse misunderstood the order in regard to the quantity to be used at a time. The third case died as a result of loosening of a Murphy button on the seventh day. The patient was badly nourished, and it is likely that union was retarded.

In the first of these three cases a gastroenterostomy should have been made, because the patient's condition was greatly reduced on account of the complete obstruction of the pylorus by the carcinoma, but the tumor seemed so completely confined to the stomach that it seemed as though its removal might result in a permanent cure. In the second case, the death was plainly due to an accident, which could have been avoided. In the third case I believe that my technic was at fault.

There were seventeen gastroenterostomies for the relief of non-malignant obstruction of the pylorus. Of these sixteen recovered and one died. The latter was a patient 74 years of age, greatly reduced in strength, with an almost complete cicatricial obstruction of the pylorus. Her death was due to exhaustion.

There were also twenty-one gastroenterostomies for the relief of pyloric obstruction due to carcinoma in cases in which a complete excision of the tumor was not possible. Of these twenty recovered and one died from exhaustion. The patient was greatly reduced on account of an almost complete obstruction of the pylorus. He was 65 years of age. The autopsy showed perfect healing of the anastomosis and there was no peritonitis.

During the same time I have operated on a number of cases at two other hospitals, but I have not had the necessary time to review the histories of these cases, and consequently this paper was based on the observations made in the study of this series of fifty-six cases.

Regarding the immediate results, I would say that the cases of obstruction due to carcinoma experienced great relief, many of them being not only freed from pain and nausea and vomiting, but gaining very greatly in strength, and almost all expressed their great appreciation of the benefits of the operation. The ultimate results in these cases will be reported later.

In the non-malignant cases I think that there has been great benefit in almost every case. The ultimate results will also be reported later.

It is likely that a larger experience will modify many of the opinions expressed in this paper, and it is not intended that it should carry great weight.

710 Sedgwick Street.

DISCUSSION

ON PAPERS OF DRS. KNOTT, NILES AND OCHSNER.*

Dr. F. Wyllis Andrews, Chicago—It must be admitted that American surgeons have been backward and that they are following in the steps of the Germans in developing gastric surgery. But, of course, we all know that the world recognizes the excellent pioneer work of the American surgeons in intestinal surgery. The evolution of gastric surgery will take over a large number of men, who formerly treated the cases medically, into the surgical domain. We used to accept those cases when they were sent to us by the interne for operation, which was very rarely. Now we assume that the pathology, symptomatology, etiology and indications for operation belong to our field. There is no more reason why a gastric ulcer should be classed as medical than there is why the same condition on the leg or on the tongue should be considered a medical disease. Dr. Dunsmoor expressed his surprise and disapproval that so many surgeons were willing to enter on operative work in the lower abdomen, and were so much afraid of the work above the umbilicus. I remember reading the statement by Dr. Willoughby Furness that the proximity of the solar plexus made surgery in the upper abdomen more dangerous from the standpoint of shock. Now this false conservatism or timidity deters operators in this field, but when you consider the anatomy you will find that it is easier to repair the stomach walls than it is to do the same in one of the small intestines. It is a fertile field for the operator. What are the indications for operative interference in stomach disease? The indications are not simply existence of chronic stomach disease, whose nature we can not determine. I think the trend of modern surgery is in this direction: when we have a case of chronic stomach trouble we operate for diagnosis. How many times a dyspeptic patient will be operated on, say for hemorrhoids, then sent to some specialist, who will remove an ovary; then you may send for some one who will anchor a floating kidney; then for some one, who in despair will remove the appendix; and after all this the patient comes back to you as bad as ever. But if the patient had been sent to a surgeon who would have performed a gastroenterostomy in the first instance, you would have cured the case. Dr. Ochsner spoke of a number of cases in which he had operated for pure gastric pain. Probably he now performs a gastroenterostomy on all cases of obscure gastric pain and cures a large proportion of them. Now, I think we must all recognize that the chain of disorders, beginning with ulcer and ending in stenosis or carcinoma, we have the same indication for early operation that we have in other abdominal conditions. There is frequently the case of the gastric ulcer, running over a period of pain, vomiting and hemorrhage, and later producing carcinomatous degeneration of the healthy tissue. Dr. Bevan has reported a case of pylorectomy for the removal of pyloric carcinoma, which commenced in ulcer of the stomach. Dr. Niles traced in his paper the history of a carcinoma of the pyloric end of the stomach, beginning, as you will find nearly every one of them, in gastric ulcer. Surgery must recognize the clinical continuity of these factors ending in carcinoma, and must operate more often in the ulcer stage without waiting for perforation, hematemesis or malignant obstruction.

Dr. William J. Mayo, Rochester, Minn.—The surgery of gastric ulcer at this time is really the surgery of its complications. This is shown by the first two papers that were read to-day in regard to stomach adhesions, pyloric obstruction, hemorrhage and perforation. It is not the gastric ulcer which we have been operating for; it is the complications of the gastric ulcer. We must keep this very clearly in mind. What are we going to do with the cases we see before the complications arise? This is a part of the subject which must be cleared up. The ulcers which produce the complications are usually in the pyloric end of the gastric cavity. The pyloric part of the stomach is the muscular part, and it is on this side that we not only get the gastric ulcer, but at least 60 per cent. of all the gastric cancers, and it is altogether probable that many have their origin in ulcer. We can not usually excise these ulcers, as they are often multiple. I have searched for a bleeding ulcer half an hour and been unable to find it, although the patient had a severe hemorrhage three or four days before the operation. The pyloric obstruction is a complication of gastric ulcer, but the ulcer is there long before you get the obstruction; so that operations on the pylorus can not cure the condition, because the ulcer does not depend on obstruction, and in many of the cases the ulcer is beyond the pylorus in the duodenum, and after plastic operations, which are intended to cure the ulcer by enlarging the pylorus, the food must still pass through the ulcerated area before it reaches the bowel.

Gastroenterostomy is the most satisfactory operation for ulcer, as it drains the stomach at a point to the left of the ulcerated portion, and if the pylorus be obstructed the cure will be permanent; but if the pylorus be open, as soon as the ulcer heals the spasm relaxes and the food passes down through the pylorus again and the fistula contracts, and relapse may occur. In such cases resection of the pyloric end of the stomach or the ulcer bearing area will be best, as recommended by Rodman.

Just a word in regard to cancer. Our only reasonably satisfactory operations for this condition have been extirpation. The operation for pyloric growth usually is not difficult, and by removing all of the lesser curvature the pylorus and the body of the stomach to the left gastroepiploic vessel, all of the lymphatics will be removed and the remaining portion of the stomach may be expected to remain free, as it is isolated from the pyloric end by reason of a separate vascular and lymphatic arrangement. In 27 resections of the stomach for cancer, 5 died from the operation, one died later from another cause; but of the 21 that recovered, the average length of life was over a year, one living over three years and two alive and well over two years.

Dr. Carl Wagner, Chicago—Three cases of so-called inoperable carcinomatas, which have occurred in my practice, come to my mind. The most important one afflicted a woman aged 53. She was emaciated to a skeleton and had a tumor of the size of a fist in the stomach region, which first appeared about a half year previous, growing steadily since. The patient presented all the symptoms of carcinoma of the stomach, such as the presence of lactic acid, absence of muriatic acid, emaciation, vomiting and pains. Several surgeons were consulted, who all concurred in the diagnosis of inoperable carcinoma of the pyloric end of the stomach. The patient had another tumor in the inguinal region, below the Poupart ligament, also the size of a fist, which was diagnosed as a lipoma, and, of course, not brought into any connection with the tumor visible in the stomach region. When she came under my care I also was of the opinion that I was confronted with inoperable neoplasm of the stomach, and took therapeutic measures accordingly, until one day I recollected a case of my former experience, where I found, with an exploratory laparotomy, a fatty tumor, originating in the ligamentum teres, hepatis suspensorium and overlying parts of liver, stomach, gall bladder and part of ascending and transverse colon, which caused a condition similar to that presented in the present case. Thus I resorted to an exploratory laparotomy also in this case.

---

* The papers of Drs. Knott and Niles appeared in The Journal of May 23.

The tumor, which the operation exposed, consisted mainly of omentum, which had converted part of the stomach, colon transversum, liver, gall bladder and the corresponding parietal peritoneum, through exudates and adhesions, into one solid, unique mass. It could be removed very readily, in spite of a few difficulties, and careful examination showed otherwise absolute normal conditions of the organs involved. There were no signs of old ulcer cicatrices in the stomach in spite of the fact that such could have been suspected to exist on account of pains, which the patient stated she had suffered during nineteen years previous to the first appearance of the tumor. This latter misled the physicians to conceive the theory of ulcer, cicatrix and subsequent carcinoma, just as in [illegible]

I closed the abdomen, somewhat disappointed at not having found any explanation for the development of the inflammatory condition of such grave bearing on the whole organism. However, when I proceeded to extirpate the alleged lipoma, which, as above stated, was located at the region of *the fossa ovalis femoralis, everything became clear to me.* After freeing it from its covering, it unfolded itself just like a lipoma arborescence, such as we find in the knee joint and with a pedicle as thin as a lead pencil entering into the femoral canal in the peritoneal cavity. On traction it proved to be in connection with the omentum and represented an elongated end-piece of it, which had slipped through the femoral ring in the form of a femoral hernia out of the abdominal cavity, and developed outside of the femoral ring into this large tumor.

The weight of this extra abdominal tumor caused, with every motion, especially when walking, a pulling, jerking sensation at the insertion point of the large omentum, namely, at the large curvature of the stomach, and thus produced intense pains. In the good old German style, hot plates, hot poultices and all kinds of other counter-irritants were applied frequently to the stomach region, during years, with the result that in time local peritonitis, with adhesions and exudate masses, developed. Seven years have elapsed since the operation and the woman is still enjoying very good health. Consequently, the alleged inoperable carcinoma of the stomach, which had reduced the patient to skin and bones, and, undoubtedly, would have terminated her miserable existence within a few weeks on account of marasmus, was no carcinoma at all.

This case serves as an excuse for a plea for greater frequency of exploratory laparotomy in such so-called absolutely hopeless cases of inoperable carcinoma of the stomach.

Dr. William L. Rodman, Philadelphia—There is no more important subject at the present time than gastric surgery. Here in America we have been a little slow in moving along in this direction. I think that Dr. Mayo admirably summed up the situation when he said that the surgery of the stomach is principally the surgery of the complications of ulcer rather than the first ulcer itself. I think we should always keep in mind that it is the complications resulting from gastric ulcer that require operations on the stomach. Therefore, as he says, the real question is as to what to do with the gastric ulcers, if they can be diagnosticated sufficiently early to render excision possible. There is no doubt that we will come very early to the excision of the ulcers before complications take place. It has already been done in an increasing number of cases year by year, and I feel that in time the treatment of gastric ulcer will be partial gastrectomy, and that the mortality will not be more than 5 or 10 per cent. Taking all the early operations done during the past fifteen years, it has not been more than 15 per cent., and surely at the present time it should not be more than one-half of that.

I would like to call attention to one point that Dr. Knott did not refer to in his paper. These adhesions between the anterior wall of the stomach and the abdominal parieties, which would seem to be easy and safe to break up during the operation for gastric ulcer, do not always prove so. Thus, Hofmeister has said that adhesions should always be picked apart very carefully, having in mind not only the possibility, but the probability of tearing into the wall of the stomach itself.

On one point I would rather differ from Dr. Niles. He speaks of the inadvisability of excision in a majority of instances because of the fact that multiple ulcers may exist. That is true undoubtedly in many instances, but it does not occur sufficiently often to deter one from doing a partial gastrectomy if there is a well marked tumor, and it may occur even in benign as well as malignant disease. Even if the small ulcer is overlooked, no harm is done. We must remember always, as Dr. Niles and Dr. Murphy and Dr. Ochsner have said, that there always is a marked tendency to the development of benign disease in the stomach, when there has been chronic disease. Some go so far as to make the statement that at least 50 per cent. of all gastric ulcers go on and develop into carcinoma, and we must all admit that a great number do, and it is for this reason that partial gastrectomy, which is not much more dangerous than gastrojejunostomy, is of much more value. I also wish to say with Dr. Ochsner, that we owe a great deal to Dr. Mayo in perfecting anterior gastrojejunostomy. There is no doubt that the anterior operation will closely rival the posterior method, and there is no more reason why the vicious circle should occur when the anterior operation is done, than when the posterior is performed. Personally, I have always employed the latter operation. It seems to me to be the most anatomic, and the majority of writers prefer it to the anterior. The anterior operation is of so much advantage early in the breaking up of these adhesions, that if it can be done without the vicious circle (and I believe it can), it will certainly be used far more in the future than it has in the past. I have no doubt that it is very important that the lowest point on the wall of the stomach be selected, where drainage can be easily established, and in that manner I am sure that the vicious circle will be avoided. I believe that with the operation as performed by Dr. Mayo, or by Dr. Van Hoeker, there will be in a certain number of cases the vicious circle, but these cases must be subsequently met by entire anastomosis.

Dr. A. H. Cordier, Kansas City, Mo.—If we could locate the position of the ulcer, on first thought it would seem advisable to excise it, but when we take into consideration the pathologic changes, the difficulty of locating the ulcer at the time of the operation, the inability to define its limit, the numerous vascular adhesions to surrounding organs and the slowness with which scar tissue heals, this idea is then dispelled and some other procedure suggests itself that would be equally efficient and less dangerous. This operation I believe to be preferably gastroenterostomy. I have performed a number of these operations. The majority of them have been performed in the anterior wall of the stomach. In none of my cases have I had any trouble from the so-called vicious circle. It is very essential that the opening in the stomach should be at the most dependent point. This feature of the operation I called attention to some eight years ago. Many of these cases at the time of the operation have been erroneously diagnosed as malignant, and even during the operation the indurated mass surrounding the side of the ulcer has been misleading.

TUBERCULAR GLANDS OF NECK AND OTHER LYMPHATIC ENLARGEMENTS.

There were five cases of tubercular glandular enlargement of the neck which occurred in cases with distinct tubercular history. Three were absolutely inoperable, because of the extent of the glands involved, and two had recurred after operation.

Case 2.—The first was a male, 21 years of age. He had been operated on five times in five years. The glands enlarged in February of each year. He was referred to me by the surgeon under whose care he had been. At this time glands had developed in the wound of the last operation before healing had taken place, with other enlarged glands on both sides of the neck; two were discharging sinuses, and there were ugly scars from previous operations. After a few weeks' treatment with the ray, the glands emptied completely, wounds healed promptly, sinuses closed and scars of five different operations were almost completely carried away and bleached the color of the normal skin. The patient has passed his critical season; this year (the first time in five years) absolutely free from any recurrence.

Case 3.—Another operable case was that of a female, aged 24, suffered with a discharging gland, also an ugly scar, attached to the hyoid bone and made more conspicuous by the motion in swallowing. After six irradiations, a strap of adhesive plaster was placed over the gland and sinus to prevent motion and opening of the sinus. Healing took place in six days. Six months have elapsed since this treatment was given, and there is, as yet, no sign of recurrence.

In the other operable cases, after ten days' treatment the glands were completely reduced.

In the two inoperable cases, the necks have diminished about two-thirds in size and, as they have caused no further trouble and both patients are at work, they do not see the importance of further treatment, so it has been discontinued.

My experience with these cases has been as gratifying as with any disease yet treated. If such glandular enlargements can be slowly emptied in nature's own way, radiotherapy may have the preference over operative interference, removing some of the glands, thereby throwing more work on the remaining ones, which are more liable to become enlarged.

TUBERCULAR JOINTS.

Case 4.—There are two cases under this head which I would like to report. One, tuberculosis of the knee joint, with tubercular history and other tubercular complications. The condition had existed for four years. There was thickening and induration of the joint, distinct rice bodies in a small amount of fluid could be felt. Patient was able to get about for only a short time, when the leg would give out completely.

With intermittent periods of a week, irradiation was continued through five months, when patient was discharged clinically cured; deposits were all carried away, except slight thickening; pain and tenderness completely relieved, and the patient was able to get about all day without discomfort. He had had everything in the way of treatment, except resection.

Case 5.—The other case was one of tuberculosis following an injury to the bones of the hand. Large areas of dead bones could be felt with probe, and there were four discharging sinuses. With irradiation, sinuses all healed, pain and tenderness disappeared and there was fairly good motion. Patient was constantly watched by his surgeon, who was ready to scrape the bone, but this was not necessary.

Dr. John B. Murphy of Chicago reports similar cases, with good results, in tubercular granuloma, or Pott's disease.

One other result in radiotherapy and a condition which has caused probably all of us more or less anxiety is dermatitis or burn.

In many of the rapidly recurrent cases of cancer the best results are obtained by powerful stimulation, even burning if necessary. A year ago I was giving such cases only one short exposure a day, while now I give two shorter treatments daily for a week or ten days. In treating such a patient it is necessary, in fact most important, that he be told at the start what to expect, so that he may be prepared when the dermatitis appears and not be frightened into giving up the treatment and consulting another physician who is not familiar with the action of the ray. The news of a terrible burn soon spreads, and injures your reputation as an operator, when, in reality, the result obtained is the desired one. This case, I am happy to state, was not one of my own, but was referred to me for diagnosis.

The patient was a male, 74 years of age; general health, good; no history of cancer in family, but gave history of blood poison, resulting from the prick of a rose-thorn, on the hand. After acute symptoms of poison subsided, the wound refused to heal, though a similar lesion on the leg healed promptly. He was advised by a surgeon to have the rays applied to the ulcer, then about the size of a half dollar. Long exposures were given, and after the fourth, dermatitis appeared, and lasted a month, with slight improvement in the ulcer. Treatment was resumed, and after the eighth exposure dermatitis again occurred. The hand was greatly swollen, and very painful, with a gradual increase in the size of the lesion and increased pain.

The patient was first brought to me Dec. 14, 1902. The hand was then photographed. The ulcer had no appearance of epithelioma. It looked most healthy, with bright, shelving edges. There were areas of bone and tendon exposed. The condition of the skin about the ulcer was that of dermatitis, broken and parched in appearance. A static production of the ray ten inches from the ulcer produced almost instant irritation. Amputation was advised, and the patient made a good recovery.

Microscopic sections were taken from different areas of the ulcer. These revealed squamous epithelioma, with most unusual increase in the fibrous tissue which the pathologist attributed to the action of the rays and the condition, to him, was a new one.

I deem this case idiosyncratic to the rays. The mildest medication caused instant burning.

There was no sugar in the urine, and from previous history, clinically, it was not an epithelioma.

In conclusion, conditions demanding a long series of treatment with the rays, overstimulation invariably occurs if periods of vacation are not given. It develops in the old and paralytic more quickly than in the middle aged or young. The most gratifying results may be obtained in radiotherapy by the operator who carefully studies his apparatus, the tube he is using and the effect of the ray on his patient; yet, on the other hand, if he neglects this strict attention to every detail, or leaves his work to an inexperienced assistant, disappointment and failure will be the outcome.

DISCUSSION.

Dr. C. E. Skinner, New Haven, Conn.—Dr. Varney's paper and the conclusions he deduces from a clinical experience which accords very closely with all who have been using the x-ray in these conditions are very valuable. There is no point on which I saw occasion to disagree with him, but he did not mention the effect of the x-ray on the healing process in fresh operation wounds. As a rule the x-ray is considered stimulating to fresh wounds, but occasionally we get cases where the action would appear to tend toward retardation of the healing process. Two such have come to my notice. One was an amputation of the breast for fibrosarcoma, where we also removed the axillary glands which were involved. The rays were applied immediately after the operation, and after about four applications the tissues took on a dark appearance resembling gangrene. The rays were immediately suspended and not applied again for two weeks. Meanwhile the clots which had formed under the flaps did not absorb, and it was necessary to take out some stitches and remove them. It took this case three weeks to heal when it should have healed in ten days. Another significant case was related to me by Dr. M. M. Johnson, Hartford, Conn., who had a patient with a carcinoma of the breast, which he rayed for three weeks previous to operation. At the time of operation he observed that blood did not spurt from the arteries as it ordinarily does, but merely flowed, as when a vein is cut. All these facts are significant of the conclusion that the x-ray exercises an influence on the circulatory function whereby the blood supply is lessened, and whether or not we are sometimes going to get into trouble with gangrene when we ray freshly-cut surfaces I think is a problem worth bearing in mind.

I would like to contribute a little to the therapy of the x-ray by exhibiting some photographs of a case of ichthyosis, occurring on a boy aged 15. When he was two weeks old ichthyosis began to appear and has been present ever since, the areas affected having increased. The case came to the clinic of the Yale Medical School and was exhibited before the New Haven Medical Society by Professor McDonald, the dermatologist of the institution. My assistant in radiotherapy, Mr. William W. Herrick, New Haven, was present at the meeting and saw the case. It occurred to him at once that if the x-ray could influence malignant epithelioma, would it not also be capable of influencing benign epithelioma. Professor McDonald consented to the trial being made and Mr. Herrick rayed one hand while Dr. McDonald treated the other hand with green soap. This treatment was begun about ten weeks ago. Mr. Herrick will report the case in full later on. The credit for the conception of the idea that the x-ray might be of benefit in this case and for the work actually performed belongs to him. But he has courteously permitted me to bring the case to your notice at this time.

The photographs show the conditions before and after treatment. The layers of scales on the hands and feet were half an inch thick. The right hand was rayed, the left hand treated with green soap. The back of the right hand is now perfectly normal, the scales have entirely disappeared from the backs of the fingers and the greater part of the inside of the hand. In the left hand, treated with green soap, no change has taken place except that a small portion of the scales here and there has come off. Another noticeable fact is that where the scales came off of the right hand, treated with the rays, no irritation followed, the skin appeared pink and normal and soft. Where the scales came off from the left hand, by the action of the green soap, the skin underneath was white and presented the appearance of maceration. Immediately after the sloughing of the scales on the left hand the skin which was exposed thereby would harden and crack, and the hand is now rigid. He can not use it because of the pain excited by stretching the hardened cracking integument, while the right hand is perfectly pliable and flexible. Although this case at the present time is more a curiosity than a demonstration, yet the results are significant from a therapeutic standpoint and give ground for the hope that something of use to the sufferers from ichthyosis may be gained in the future from x-ray therapy. I will say in closing that this is the first time within the memory of the patient that any portion of his body which was affected by the disease has become free from the characteristic epithelial accumulations.

DR. JOSEPH ZEISLER, Chicago—This subject was up for discussion a year ago, and without doubt it has been discussed since again and again. I have put myself on record with my personal experiences in radiotherapy in a paper which I read last September before the American Dermatological Association. We are living in a period when we may expect every few months from various observers comprehensive papers such as Dr. Varney's, showing the effect of the rays in all sorts of conditions. Whoever works with the rays will continually develop a justifiable enthusiasm which will prompt him to publish his reports, and I look on the report of Dr. Varney in that light. On the whole I agree with everything he has said, and shall be the last to doubt the results he has reached. I was rather surprised to hear Dr. Varney suggest the removal of the hard edges of an epithelioma with the curette first and the use of the rays afterward. It seems to me this would antagonize the principle of radiotherapeutic measures and would turn patients from the treatment by rays, because they do not care to have a cutting operation done. The fact is, any epithelioma on the surface can be removed by the rays alone without any other measures, if the proper method is pursued. It is by no means a tedious affair. In my experience, which covers perhaps thirty cases of epithelioma of the skin, 13 to 14 applications were always sufficient to remove our epithelioma.

In regard to the cases of acne I would suggest to the Doctor that if he will extend his field of work to all sorts of acne he will be as much surprised at the result as in the indurated variety. The treatment by radiotherapy of all forms of acne has come to be my first choice. The results can not be compared to any other treatment, and it makes the internal treatment of acne almost superfluous.

I quite agree with Dr. Varney as to the difficulties in cases of hypertrichosis. At the same time I have had positive success with several cases, which have now remained free of hair for over a year. No one should undertake to remove hair with the promise that its removal would be permanent. It will return, but by repeated exposures, frequently before the new growth has started up you can keep the capillary blood vessels in a state of paresis, such as is responsible for the loss of hair.

In this connection I would point out one feature we want in future publications of this kind—not to discredit Dr. Varney's contribution but to ward off similar papers in the future. What we want from now on are reports on x-ray treatment after the observation of the respective cases for a year or two. Sometimes we have marvelous effects in psoriasis. I can clear any patch up in three applications, but in a few weeks the psoriasis returns. We want to know under what conditions this treatment offers permanent results. That it offers temporary results we know, but it seems to me that from now on we should only report results which allow us to look back for a period of several years.

DR. L. DUNCAN BULKLEY, New York—I wish to say that I am foolishly enthusiastic about some results I have obtained with this method. A patient in the skin hospital had her foot so affected that it was scraped a dozen times under ether, scraped down to the bone, and it would heal up for a month or two. Everybody who had seen her had tried everything they knew of for her relief, but she was crying with pain, and sometimes she used several grains of morphin, the pain was so great. A dozen or so applications of the x-ray cleared up everything entirely from her feet so that she could at once be up and around the clinic. It was a marvel to me. It exceeded anything I could have imagined.

I think it is interesting to mention our methods as to time, as to distance, as to the revolutions of the machine, and give some idea of the strength we use. This would help us all. I burn some few cases mildly. An epithelioma is better to be burned mildly than not. As to scraping, I think it is desirable, as it saves several applications of the ray.

DR. R. R. CAMPBELL, Chicago—Dr. Zeisler asks for data that have existed some months, and I think I can supply this as regards one disease. I believe I was one of the first to use the x-ray in the treatment of acne and reported some 15 cases in THE JOURNAL of the American Medical Association. Some of these cases have now gone on for almost two years without recurrence of the acne. In all of these cases all treatment other than exposure to the x-ray had been absolutely thrown aside and the action of the x-ray depended on entirely for the results obtained as reported in that article.

There is one disease in which I believe it is imperative to burn, at least in my experience it has appeared so. In three cases of tuberculosis verrucosa cutis which I have treated with the x-ray I could not get a semblance of a result after repeated exposures until I made it a point to burn. After the burn had been obtained the disappearance of the disease was very prompt. In cases of acne, of lupus, of hypertrichosis, I have not found it necessary to burn, nor have I yet produced in any patient a burn in which my efforts were not bent particularly in that direction and in which the burn was sought. As Dr. Varney has said, we must recognize the idiosyncrasies which exist in different people. This is the rule regarding the *x*-ray as well as any other therapeutic agent we may use.

In cases of epithelioma treated with the *x*-ray, which have been operated on—I am speaking of cases of epithelioma which fall into the hands of the dermatologist who finds it necessary to resort to surgical procedures—the time to institute the treatment by the *x*-ray is not after the tissue has hardened, but within two or three days after the operation has been performed. I think that is not only the case in epithelioma, but it is the case in all malignant diseases. In cases of deeper and malignant troubles, however, I question very much the ultimate efficacy of the *x*-ray. We do get temporary results. But it is a question in my mind as to whether or not we promote a metastasis, and when reaction does take place the growth goes on with a rapidity that has been unknown to us after any other procedure.

Dr. G. P. Edwards, Nashville, Tenn.—One point touched on by Dr. Bulkley I wish to emphasize particularly, that is a more accurate technic of *x*-ray therapy. It is the custom of most of us to use our cheaper non-regulating tubes for treating these skin lesions, because they are cheaper and are not so easily destroyed. I think this is a mistake. I think we should know exactly the condition of our tube and what it is doing. In this work we should be able to maintain the same degree of exhaustion for the same class of cases. The variety of effects we are getting in these cases is not so much due to the idiosyncrasy of the case as to the idiosyncrasy of the operator in using tubes of different degrees of exhaustion. It has been my privilege to study this particular point, so when I do get a result I know how I got it.

Dr. A. H. Ohmann-Dumesnil, St. Louis—The important point in radiotherapeutics is technic, also the proper lamp glass, whether hard or soft. I have had a very unfortunate experience in the effects of radiotherapy. A young lady of Memphis, Tenn., was treated by Dr. Lassar of Berlin, and when I saw her she had an *x*-ray burn nearly healed, but with a very thin scar all over the face. She came to me to be relieved of the scar. I have seen a case where the foot had not been covered by lead in which there was an affection of the metatarsal bones. Those are cases I think it is well to speak of with this idea only, not to declaim against *x*-ray therapy, but as a reminder to all to be careful in their technic in every detail in order to avoid such consequences, which are difficult to ameliorate or make completely well, some of them requiring months and months. The case of injury to the metatarsal bones has been of nearly nine months' duration, and the man can not walk with ease yet. This is not encouraging to the use of *x*-ray therapy. You may say it shows great negligence on the part of the operator, but he should not have been negligent, and this part of the technic should not be forgotten.

Dr. J. H. Duncan, St. Louis—I have had considerable experience with the *x*-ray treatment in my dermatologic work, and have had my share of success, not only in new growths, but in ordinary skin lesions. The longer I use the ray the more careful I am in the selection of my cases, and I am afraid if we are not careful before long the dermatologist will be relegated to the *x*-ray specialist, and the real diagnostician, the scientific dermatologist, will have to take a back seat. I hope, then, that we will not attempt to treat all of the skin lesions we come in contact with by the ray, but select our cases and rather use the *x*-ray as an adjunct to other treatment. While we know, for example, that the *x*-ray may relieve permanently a new growth, realizing the length of time it may take to produce that result, I am of the opinion that curettement with the application of a plaster, or some kind of operation, then the healing of the wound by the *x*-ray would not only facilitate matters, but would probably make a more permanent cure. I was, and am, to a large extent, enthusiastic in this matter. I have had success in cases of acne, infiltrated thickened chronic eczemas, hypertrichosis, etc. My experience with the ray has been most gratifying in breast lesions and in the treatment of epithelioma or cancer of the lip. I have had experience in the treatment of a small affair no one has mentioned, but it was a most annoying affection. It was a case of verruca, 30 or 40 warts on the back of the hand. The result in that case was satisfactory. Of course, we would not use the ray for one or two warts, but the entire back of the hand was covered with verruca.

We can all give our experiences in these things, but let us not get too enthusiastic about the *x*-ray to the exclusion of other old and well-tried remedies.

Dr. J. B. Guthrie, New Orleans—There is a little point in *x*-ray technic that I worked out and subsequently found mentioned, but no details given, in Williams' work. The feature of the method I refer to consists in the simultaneous use of two or more *x*-ray tubes connected to the same generating source, coil or static machine, as the case may be. I have found this procedure of especial value in the treatment of cutaneous lesions when, as is often the case, they are widely disseminated or located on opposite sides of the face, rendering treatment by a single exposure impossible. Where two tubes are run at the same time two exposures of the same patient are rendered unnecessary, for all of the diseased area receives treatment at the same time.

I have a tube stand with arms of the usual double-jointed type with two arms instead of one. Each of these arms carries a tube which is connected to the proper terminal of the machine. If we call the tubes A and B, the connections are as follows: The cathode of tube A is connected to the cathode of the generator, and the anode of tube B is connected to the anode of the generator. The anode of tube A is then connected with the cathode of tube B by a piece of flexible wire. This puts the tubes in series, and connected in this way each tube takes the current it needs and allows the excess to pass on to its fellow. It is not essential that both tubes be of the same vacuum, although the tubes operate best when this is the case. A high tube and a low one will both glow provided that the aggregate resistance of the tubes does not exceed the sparking capacity of the generator. It is necessary to use a spreader that is long enough to prevent sparking across from one wire to another. When only one of the tubes is to be used the other is short-circuited by connecting both wires leading to it to one terminal. It is sometimes desirable to have a high tube and a low one on the stand. Then when one tube is in use the other swings out of the way.

The device I have described has been very useful to me, and I consider it a time-saver. I have never utilized it to treat more than one patient at a time, but this is possible. It is most useful in skin work for the reasons I have named. I mention it with the hope that some of the members of this Section will find use for it also.

Dr. J. N. Roussel, New Orleans—I want to suggest the use of oxygen in the treatment of parasitic skin diseases by the *x*-ray. In my experience oxygen in spray, which we might obtain either by means of a bag of oxygen or the static breeze, accelerates the action of the ray materially in the treatment of ringworm and sycoses.

Dr. H. R. Varney, Detroit—In reply to Dr. Skinner's inquiry as to the action on the normal tissue, I would state that as far as I have been able to determine it is a specific cell stimulant, producing a stimulation that is characteristic in itself, an inflammation that exists for days and weeks, and even months.

In answer to Dr. Zeisler regarding the scraping of the hard epithelial border, I do that in cases where they wish to gain time. I hope I have not appeared too enthusiastic; Dr. Zeisler's criticism is a timely one. In my paper I have reported only one case that has occurred in my work since the first of January. I have been operating for two and a half years and have given about ten thousand exposures.

I believe I mentioned verruca in my paper. I have had some very interesting cases in that line with very gratifying results. They, of course, sometimes disappear like magic with no treatment, yet are troublesome in certain localities. The multiple tube I have never used, but can readily see that in acne and other conditions we would gain time with it.

Dr. Bulkley's *suggestion* for more knowledge regarding would be of great value to us all technic in this line of work would be of great value to us all if it could be given with some definite rule; but as operators, we all know that there is no definite dosage in giving the ray, as no two tubes produce the same ray; no two patients react the same to the ray; nor does the disease under treatment. Therefore, each operator must, to be successful, establish his own technic, by carefully studying his apparatus, the tube he is using, the patient under treatment and the disease being treated.

CLAMP FORCEPS FOR REMOVAL OF NASOPHARYNGEAL TUMORS.*

E. FLETCHER INGALS, M.D.

CHICAGO.

The report of the following case is made to illustrate the advantage of having a suitable clamp to aid in the removal of nasopharyngeal tumors by the galvanocautery and to call attention to an instrument which I believe will be found advantageous in very many cases. It would also aid in the removal of some growths by the cold-wire snare.

The patient, E. J., a young man 22 years of age, had been troubled with partial occlusion of the nares and the necessity for frequently clearing the throat for about five years. Latterly, there had been complete occlusion of the left naris, but the right was permeable a part of the time. There had also been frequent bleeding of the nose. The patient's personal and hereditary history gave no clew to the cause of the trouble. The thoracic signs were normal. On examination of the nares I found the right side three-fourths closed by swelling of the inferior turbinated body; the left side was free at its upper and front part, but was completely closed posteriorly by a growth in the nasopharynx.

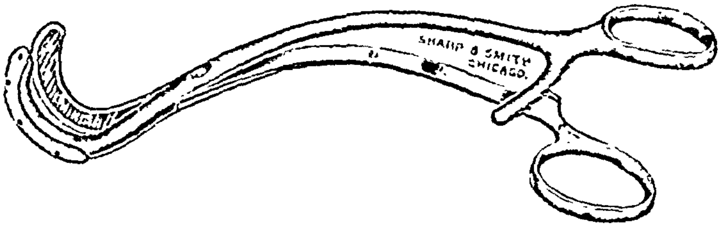
On rhinoscopic examination, I discovered a fibrous tumor with a broad base attached to the vault and posterior part of the nasopharynx, measuring about 1½ inches in length, and about ¾ of an inch in its other diameters. This growth three-fourths filled the nasopharynx. Its surface was smooth and marked by several enlarged blood vessels. It was hard to the touch and firmly attached, with but a slight groove at the lower part between the tumor and the pharyngeal wall, so that a wire could not be made to hold.

The left naris and the nasopharynx were anesthetized as thoroughly as possible with cocain and through the left naris I passed into the nasopharynx and brought out at the mouth, a No. 5 soft male catheter, both ends of which were then held to the left. A similar catheter of different color was next passed through the same naris in like manner and both of its ends were held to the right. The two ends of a long No. 20 platinum wire were then introduced into the ends of the catheters that came out of the mouth and passed back until they came to the turn in the nasopharynx. The catheters were then drawn out through the nostril until the ends that protruded from the mouth were out about four inches nearer to the lips. This caused the wire to make the turn in the nasopharynx, after which both ends were easily pushed in until they came out of the catheter through the nostril. I then passed the clamp-forceps through the mouth, into the nasopharynx and crowding upward and backward grasped the tumor firmly and locked the clamp on its base. Next the loop of wire protruding from the ends of the catheters out of the mouth was carried under the handles of the forceps and drawn back into the mouth so that it must of necessity slide up behind the blades. The catheters were then removed, the wires being carefully held so they could not become crossed in the naris. Next, these wires were slipped through the tubes of a galvano-cautery ecraseur and the electrode and wires were made fast to the handle. The loop was now made tight on the tumor by turning the rachet on the handle.

I then told the patient that as we burned off the tumor it would necessarily cause pain, but I wished him to stand it as long as he could, and that I would cut off the current the instant he requested it. With this understanding, the current was turned on, the loop heated and allowed to burn into the tumor for about three seconds when at the patient's signal the current was cut off. He was allowed to rest for a minute or two and then the current was again turned on in the same way, the rachet being tightened in the meantime. Thus I proceeded burning into the base of the tumor about a sixteenth of an inch at a time until it was completely cut off, without very great discomfort to the patient and without hemorrhage.

In this case the clamp was of signal service because it would have been impossible to engage the tumor in the galvano-cautery loop without it. I believe that the instrument will greatly facilitate the removal of many of these tumors and will make the operation more thorough, even when they might be removed without it, for with it the tumor can be secured at once and the loop of the snare, when carried under the handles and drawn back into the mouth, must necessarily engage the base of the tumor.

The nasopharyngeal clamp forceps has the general form of Loewenberg's nasopharyngeal forceps. The blades, however, are longer and much more curved. The curved portion, which is two inches in length, is so shaped as to accurately fit the vault of the pharynx in the ordinary adult; each blade is protected at the back and outer side by a piece of ivory, so that a short circuit will not be made when the galvano-cautery snare is applied, and the roughened faces of the blades are each provided with four short sharp spikes to prevent slipping. When the instrument was first made the curve was not so great as at present and the blades were not provided with the spikes. I found that it did not accurately fit the vault of the pharynx, and furthermore, that it would slip when the tumor was grasped. The present form appears to meet the conditions perfectly. The handles are provided with an arrangement for locking, similar to that used with many other forceps.



Author's clamp forceps for removal of nasopharyngeal tumors.

34 Washington Street.

Sudden Blindness After Paraffin Injection.—Dr. Lee Maidment Hurd reported to the Section on Laryngology and Rhinology of the New York Academy of Medicine on May 27 a case in which there had been instant loss of vision following a paraffin injection for nasal deformity. The patient was a man of thirty-three years without any history of syphilis, whom he had given, some months previously, two or three injections of paraffin with the object of improving a nasal deformity. The man returned requesting another injection, and while this was being given he became blind. Ophthalmoscopic examination revealed the typical appearance produced by embolism of the central artery of the retina. While the possibility of this accident being a mere coincidence was freely admitted, the opinion seemed to prevail that it was directly connected with the paraffin injection. The blindness is permanent.

LECITHIN AND ITS THERAPEUTIC USE.

Although lecithin is a constant constituent of all kinds of cells, and therefore an ingredient of all foods, the manner in which it is absorbed and utilized is unknown. Its constancy in the cells, both of animals and plants, and the large amounts that exist in the central nervous system, are sufficient evidence that it must play some important part in life processes, but what these are is little more than surmised. On the other hand, its composition, although very complex, is well understood. Shorn of technicalities it is a fat which has had one of the three fatty acid groups replaced by phosphoric acid, to which is attached a nitrogenous body, cholin. It is the presence of this last group that makes the substance of particular interest, for the body cholin, although not very toxic itself, is easily converted into an extremely poisonous substance, neurin. It may also be oxidized into a very poisonous body isomeric with muscarin. The changes that lecithin undergoes when taken into the alimentary tract are far from clear. That it is absorbed in the same manner as other fatty bodies is possible, but, on the other hand, the presence of the cholin-phosphoric-acid group may cause it to behave in an entirely different way. In other words, it is not known whether the lecithin that is found in the tissues comes directly from the food, or is built up by the cells where it is found.

As to its functions, the nature of its composition suggests that it is not merely a source of energy, as are the fats, but rather that it plays an important rôle of some kind. For this idea speaks also the fact that it is most abundant in the brain and in egg yolk. The significant fact that the substances that act as anesthetics are those in which lecithin and fat are soluble, as chloroform and ether, led Hardy to build up his theory of the importance of lecithin in the conductivity of nerve impulse. When the lecithin is dissolved by the anesthetic, or at least has its physical condition altered, the nerve fibers can no longer transmit impulses; when the anesthetic has been eliminated the lecithin returns to its ordinary conditions and nerve function is restored. In another direction its importance has been shown by Kyes. He found that red blood corpuscles contained something that acted in the same way in causing hemolysis as did the important and mysterious "complement," and later it developed that this active constituent of the red corpuscles was lecithin. The greatest importance of this observation lies perhaps in this, that we have at last a definite body of known chemical nature and structure that plays a part in the reactions of immunity. And this, we may say, comprises practically all we know of the functions of lecithin.

It is quite possible that there are some harmful conditions brought about by lecithin through the toxicity of the nitrogenous bodies that it yields on decomposition. Nesbitt has demonstrated that cholin, and probably neurin, are produced in the intestinal canal during the fermentative processes of intestinal obstruction in animals fed on yolks of eggs. Therefore, it may well be that the lecithin of food is an important source of the poisons that are responsible for intestinal autointoxication; for there are few substances more poisonous than neurin, and 0.5 gram of the cholin is a fatal dose per kilogram of rabbit. When nervous tissue is destroyed lecithin is decomposed to a marked degree, as Mott has shown, and it is possible that with great nervous exhaustion there may be some intoxication with cholin and neurin derived in this way. A resemblance between the symptoms of neurin poisoning and those of the intoxication of fatigue has been observed by some.

With such a fragmentary knowledge as this of the metabolism and uses of lecithin it is evident that the recent development of therapeutic administration of lecithin is not altogether the result of applied science. Rather, the use of lecithin is suggested by the facts at hand, and the rest is empiricism. The greater part of the experimental work has been done by the French, and numerous reports can be found in the Comptes Rendus de la Societé de Biologie of the past year or more. They generally state that young animals fed with lecithin greatly outweigh the control animals; also, that animals infected with tuberculosis and given lecithin, either by mouth or subcutaneously, live longer than the controls. As yet there seem to be too few clinical observations to warrant the drawing of conclusions. The use of glycero-phosphates, which has long been tried, is, of course, based on the presence of this radical in the lecithin of the nervous system. A great many preparations of lecithin are being placed on the market, and we desire to call attention to the following points: First, that there are a number of different sorts of lecithin, depending either on the kind of fatty acid radical that enters into the molecule, or, as W. Koch has shown, on the nitrogenous complex which varies in different lecithins. (Koch has proposed the name *licithan* for the group.) Therefore, if one's observations are to be valuable it is well to know at least the source of the lecithin employed. Secondly, that in such foods as calves' brains and yolk of egg we have a rich supply of lecithin in a natural condition. Walther has found lecithin in the chyle of the dog, so it is probable that some at least is absorbed, but there is no evidence that the methods used for extraction increase its absorbability. Undoubtedly a good way to administer lecithin, if not the best, would be by modifying the dietary. And, lastly, that the ingestion of considerable quantities of lecithin or of foods rich in lecithin may not be entirely without danger, since at least during intestinal putrefaction, if not under ordinary conditions, highly toxic material may be formed from it.

TOXICITY AND IDIOSYNCRASY.

Nothing is more disconcerting for a physician than to have a remedy that he has given in perfect confidence of its harmlessness produce annoying symptoms or perhaps serious toxic effects. Needless to say there are cases of this kind being constantly reported, however, and only a previous knowledge of the special susceptibility of the patient will absolutely protect the physician from such occurrences in his practice. It is well known, of course, that this idiosyncrasy for certain drugs is often a family trait and, consequently, when certain substances, as quinin, for instance, are prescribed it is advisable to ask if the patient knows of any bad effects that have occurred in near relatives. The number of drugs that may produce untoward and unintended complicating symptoms is growing with the enlargement of the materia medica, and especially with the increased use of synthetic products. Some of the recently reported incidents of this kind, as they may be gathered from Squibb's Ephemeris[1] for the present year, are worth noting. Antipyrin is one of the drugs that is well known to produce unpleasant symptoms. Most of the cases reported, however, are of European origin and serve mainly to show how much larger doses of the drug are employed with comparative impunity than are usually considered advisable with us. Simon and Mahu of Paris report a case of toxic hemoglobinuria, following the administration of antipyrin, but as the young girl had been given 9 grams, nearly 140 grains of antipyrin, in four hours, this is not so surprising. Doses as high as 60 to 90 grains during the day are not unusual on the Continent, however. Professors Curschmann and Zweifel of Leipsic, thoroughly conservative authorities, administer from 2 to 4 grams, 30 to 60 grains of antipyrin in twenty-four hours and obtain with this more satisfactory results in the treatment of the fever of puerperal septicemia than with any other remedy. They not infrequently see the cutaneous rashes peculiar to antipyrin administration in certain patients, but they do not consider these a contraindication to the continuance of the drug.

Certain of the newer synthetic products have come under the suspicion of occasionally producing unfortunate symptoms during the past year. Several reports of this character in regard to heroin have been made. Dr. Campbell of Liverpool, who had been in the habit of using heroin hydrochlorate in doses of one-sixth of a grain with great satisfaction in the treatment of laryngeal cough, recently had an alarming experience with a twelfth of a grain dose. It has been found that heroin may produce a habit for which the name heroinomania has been coined, so that recent suggestions for its use in the treatment of morphinomania will have to be taken with great caution. Aspirin, a new salicylic compound for rheumatism, has given, on one or two occasions, unexpected symptoms of collapse. Trional and sulphonal continue to be reported occasionally as causes of severe prostration and serious anemia when their use has been continued for a considerable period without intermission. Some very interesting cases of poisoning from the use of excessive quantities (in each case a whole nut) of nutmeg are reported. The substance was employed in places so distant from each other as England and Australia for the purpose of producing abortion. Nutmeg is well known as a sedative, especially in Germany, and is often used as a mild hypnotic, being liberally dusted over night drinks for this purpose. There seems to be a widespread tradition as to its power as an abortifacient somewhat resembling that current in many parts of Europe with regard to the effect of phosphorus for the same purpose. The symptoms of nutmeg poisoning are those of a narcotic, though collapse, with muttering delirium, clammy extremities, almost imperceptible pulse and somewhat dilated pupils that react feebly to light are reported. The domestic use of nutmeg as an emmenagogue and as a hypnotic may occasionally, in susceptible persons, give some of these symptoms without more serious effects. Gangrene, especially of fingers and toes, continues to be reported as the result of applications of carbolic acid, notwithstanding the many warnings in this matter. Even such dilute solutions as 3 to 5 per cent. may produce gangrene if applied as a wet dressing. It is conceded now that this effect is due to a special susceptibility of the patient, rather than to the toxic effect of the drug. It has been noted that this susceptibility is occasionally a matter of heredity and that the physician about to employ carbolic acid in minor surgery can sometimes save himself from unexpected results by questioning the patient as to his heredity in the matter. Patients whose vasomotor apparatus is already in a disturbed condition, who have what is known as dermographia, or who suffer from Raynaud's disease, or Weir Mitchell's disease, even in mild form, must be guarded more carefully than others against the effects of carbolic acid applied locally. Progress in neurology in recent years shows that these affections are much commoner than used to be thought. It is said also that turpentine produces its undesirable dermatitic effects much more readily on patients who are suffering from one of these peripheral vasomotor disturbances that have just been mentioned.

It was thought for a time that lysol, the saponified product of coal tar with certain affinities to phenol, might prove a less dangerous substitute for carbolic acid. The poisoning cases reported, however, are more frequent than before. Complications from its local application are not common, but taken internally the drug can be quite as fatal as carbolic acid. Acetanilid has, of course, achieved a bad eminence in the matter of producing untoward effects. Its action in the headache powders so commonly used has brought it more and more to the notice of the physician of late years as a dangerous drug. A number of cases have been reported, however, in which its use locally as a dusting powder has been followed by rather serious symptoms. It usually produces its evil effects when used on abraded surfaces in children or the aged. When employed for the relief of the burning pain of so-called scalding in children it has several times produced affections resembling morbus cæruleus. Pyrogallol, when used locally in skin affections, still continues to be a reported source of toxic symptoms in susceptible individuals.

---

[1] An Ephemeris of Materia Medica, Pharmacy, Therapeutics and Collateral Information, vol. vii, No. 1, E. R. Squibb & Sons, Brooklyn, 1903.

"SCIENCE, FALSELY SO-CALLED."

In these days of general information, when few subjects are too recondite to be of interest to the general public, it is only natural that popular magazines should take up striking discoveries and utilize them in a more or less sensational way. It is unfortunate, however, when such articles do not convey correct impressions or approximately correct impressions of facts. There is no limit to human belief, and a certain amount of appearance of scientific accuracy goes a long way in carrying on to acceptance grossly inaccurate statements. A correspondent in the *Popular Science Monthly*, a journal which popularizes science in a legitimate way, wrote to ask in regard to certain magazine articles by one Carl Snyder, as to whether they were reliable or not. These articles are of the class of which we speak, very attractively written, with vivid descriptions of alleged scientific truths. We say "alleged" because among a certain amount of facts there are so many inaccuracies that we can not call them scientific truths. This was the view of the editor of the *Popular Science Monthly*, whose answer to the query was in part as follows:

> Mr. Snyder appears not to have had a scientific training; his articles are sensational and inaccurate. This somewhat sweeping condemnation is easily justified. Let us consider the last article by Mr. Snyder that has come to our attention, "The Mechanism of the Brain," in *Harper's Monthly* for May. It is a potpourri of truth, half-truth and falsehood concerning chemistry, physics, anatomy, physiology and psychology. Thus we are told:
>
>> Or, supposing that this special colloid can not be fixed upon as the seat of the highest powers of man, they might be thrown upon that extraordinary and rather hypothetical ether, of which physicists talk so much and know so little.
>
> Within half a column Mr. Snyder passes easily from ether to electricity:
>
>> As there is no nerve action without the evident presence of electricity, it seems probable that nerve action, thought and consciousness, and what in our present ignorance we call electricity, are one and the same.
>
> Physicists may not know all that they would like to know about the ether and electricity, but they know enough not to write nonsense about them.

As an example of a misstatement of facts, the editor of the *Popular Science Monthly* refers to Mr. Snyder's statement as to the great weights of the brains of Byron and Turgenieff, which he gives as authoritatively verified. It can be definitely said that the weight of Byron's brain was unknown, and this is also true in the case of Turgenieff. With such apocryphal data interspersed in the article as alleged facts its value can be estimated. They vitiate the whole thing. Another queer statement quoted is that individuals may measure the size of their own brains and can find the directions how to do so in any good encyclopedia or by applying to the distinguished Professor Wilder of Cornell. In regard to this the editor remarks that, apart from such indications as are given by the size of the hat, the only feasible direction would be for the interested person to commit suicide and let Professor Wilder take the brain weight afterward. As a distinguished social diagnostician has remarked in one of his recent articles, one can not make estimates of capacity from any outside measurements.

While the above criticisms state very clearly some of the defects of the articles mentioned, we could add still others, such, for example, as Mr. Snyder's statement that the brain of the savage and idiot is rather smooth, while that of the highly-developed man or woman is grooved and folded in an extraordinary way. The average reader would certainly get the impression that only highly developed people have convolutions. One would infer that the author had either never seen the brain of an idiot or savage or else he is exceedingly careless in his statements on the subject. Another point for criticism is his allegation that there are only insensible gradations from the ape to the highest type of man. The fact is that there is a tremendous gap and the missing links, for they probably have existed, have not yet been found, and what have been reported as such are very inadequate to complete the chain. The field of scientific research is an indefinite one, and we have only touched on the borders of it here and there. There are ways of making the interested public aware of some of the advances that have been made without the exaggerated or incorrect statements that are so often indulged in. It would be better for popularizers to give out imaginary accounts embodying scientific facts after the fashion of Mr. Wells or more recently of Professor Newcomb than to lay down so-called truths which have so far no known basis. A little knowledge is a dangerous thing, especially if it is incorrect, and, furthermore, what we want in popularized sciences is less assumption and more logically demonstrated and established facts. The cultivation of a moderate amount of scientific skepticism would be an excellent thing for many readers of the statements of popular vulgarizers, for, with the public as with the individual, as was said by a philosopher, "It is better not to know so much than to know so many things that ain't so."

A PATRIOT PHYSICIAN OF THE REVOLUTION.

The *American Monthly Magazine*, the organ of a patriotic society, the Daughters of the American Revolution, in its April issue gives a complete account of Dr. Lyman Hall, one of the signers of the Declaration of Independence. The Journal has in the past noted the fact that nearly 9 per cent. of the members of the Continental Congress that settled the question of our independence were medical men of the day, but this does not yet seem to be generally known. Such a man as Rush was sufficiently prominent in medicine and in the early statesmanship of the country to be remembered in both, but Dr. Hall, like Drs. Thornton, Bartlett and Wolcott, is seldom mentioned in his medical professional relations and in connection with his part in establishing the liberties of this country.

The account given of Dr. Hall shows him to have been a very striking character in his way. A native of Connecticut and a graduate of Yale College, he commenced active life as a minister and had a pastoral charge for a short time. He, however, gave up the ministry and taught school, finally taking up the study of medicine. After his second marriage, in 1757, he removed to South Carolina and later to Georgia, where he became one of the most prominent practitioners of the colony. He was also one of the most strenuous advocates of the colonial cause against Great Britain and carried his own county when the rest of the province was non-committal or not active in the cause. In fact, it was probably largely due to his influence that later the colony of Georgia joined the federation and he was one of the delegates appointed to the Continental Congress, to which he had already been elected by his own district. He was three times elected to this body and obliged to abandon his large and lucrative practice and his property, which fell into the hands of the enemy, was confiscated or destroyed. In fact he was obliged to go back to the north on account of the occupancy of the territory by the British forces, but returned a little before the close of the war. He was appointed governor of the province. After his retirement from the executive chair he became one of the judges of the Supreme Court for the county, and shortly after died, on the ninth anniversary of the surrender of Cornwallis at Yorktown, in his sixty-seventh year.

While Dr. Hall never bore arms nor was connected with the army during the Revolution, as sometimes erroneously stated, his service to his country during those critical times places him high in the ranks of those who were the founders of the republic. He was preeminently a physician, though in his versatile career he followed all three of the learned professions. We are glad to notice this biography of one who, while prominent in other ways, worthily fulfilled the function of our honorable profession for the larger portion of his active life, and his memory should be kept green by his medical brethren for all time.

THE MISSOURI AND KANSAS FLOODS.

The floods now occurring in the great Missouri Valley, which are unprecedented for the region and probably as financially disastrous as the reports have stated, have an important sanitary bearing. While the immediate loss of life has probably been somewhat exaggerated, the ultimate effects may be much more serious than at present anticipated. Few people who have not seen the effects of a flood in a thickly populated section can conceive of the unsanitary conditions that are produced. Aside from the breaking up of homes and rendering them uninhabitable, the exposure and the mental effects on the victims, conditions are left that it will take considerable time to relieve, conditions that are seriously threatening the health and general welfare of the community. The choked-up sewers and the consequent impaired drainage after such a flood in any particular community, together with the amount of decomposing matter in every way out of place, require the close attention of the sanitary authorities and their most active efforts. Add to this the lessened resources of the community to meet the conditions and the problem is certainly a serious one. The derangement and destruction of the food supply of so large an area as thus involved is an important matter as regards its bearings on the health. We trust that the authorities, not only local but state, have a full appreciation of the demands that will be legitimately made on them in the immediate future and probably for some time thereafter. It will probably require a considerable period to bring back the flooded sections into their normal sanitary conditions.

THE CHRISTIAN HOSPITAL SWINDLE.

We publish elsewhere the report of the medicolegal committee of the Chicago (Cook County) Medical Society in regard to the so-called Christian Hospital of Chicago, mention of which was made in our editorial columns two weeks ago.[1] Our mail has been flooded daily with circulars of this institution from our readers, but we have avoided saying more than we did in our editorial above mentioned, for the reason that this investigation was going on. During the time of its existence we showed up the old St. Luke's Hospital at Niles, Mich., and it is unnecessary to more than refer to what we published in the past to corroborate the findings of the Chicago Medical Society's committee. This committee is to be congratulated on the result of its work so far, and while it is of special local interest, considering that local men are being used, it is also of interest to the whole profession. One of the most discouraging things in connection with this institution and its predecessors and like enterprises, is the fact that physicians can be so easily swindled. If this were not true, then such schemes would not be paying ones. It would be interesting at this time to know how many of those who bought the old St. Luke's diplomas have them still hanging in their offices. We believe that few of the readers of The Journal will be found among the list, and we sincerely hope none of them has been so foolish as to invest in this later scheme.

Medical News.

ARKANSAS.

New Graduates.—At the twenty-fourth annual commencement of the medical department of Arkansas University, Little Rock, a class of 12 had degrees conferred on them by Governor Jeff Davis. Hon. W. M. Kavanaugh delivered the address to the class.

---

[1] See The Journal, May 23, p. 1443.

The New Arkansas Law.—The law regulating the practice of medicine and surgery became effective May 18, and in accord with its provisions the governor has appointed regular, homeopathic and osteopathic boards of examiners. Those from the regular school are as follows: Dr. Charles R. Shinault, Helena, first district; Dr. Oscar E. Jones, Newport, second district; Dr. George V. Poyner, Green Forest, third district; Dr. M. L. Norwood, Lockesburg, fourth district; Dr. Joseph P. Runyan, Little Rock, fifth district; Dr. William Crutcher, Pine Bluff, sixth district, and Dr. Adam Guthrie, Prescott, seventh district. At the first meeting of the board, May 25, Dr. Shinault was elected president, Dr. Runyan secretary, and Dr. Norwood, treasurer. The bond of the treasurer was fixed at $1,000.

CALIFORNIA.

Names Staff.—Dr. Frank K. Ainsworth, chief surgeon of the Southern Pacific Railway, has appointed Dr. Horace G. Cates assistant surgeon of the system, with headquarters at Los Angeles; Dr. George L. Hutchinson, assistant to Dr. Cates; Dr. Ernest A. Bryant, Los Angeles, local consulting surgeon, and Dr. Ernest M. Keys, local surgeon at Alameda.

More San Francisco Graduates.—Cooper Medical College on April 28, graduated a class of 45. Dr. David Starr Jordan, president of Stanford University, delivered the address.——The College of Physicians and Surgeons held its commencement exercises May 21. Dr. Winslow Anderson, dean, conferred degrees on a class of 28, and Prof. Robert E. O'Connell, delivered the address.

Committee to Investigate Tuberculosis.—At the last session of the Medical Society of the State of California, the following committee was appointed to investigate the prevalence of tuberculosis in the state, and to make such recommendations to the society at its next meeting as it may deem appropriate: Drs. F. M. Pottenger, Los Angeles, chairman; George L. Cole, Los Angeles; John C. King, Banning; George H. Evans, San Francisco, and Edward von Adelung, Oakland, secretary.

Personal.—Dr. David C. Barber has succeeded Orville R. Witherbee as superintendent of the Los Angeles County Hospital.——Drs. J. Hamilton Todd, Arthur L. Cunningham and Samuel H. Buteau, have been made members of the Oakland Board of Health.——Dr. Martin Regensburger, San Francisco, has been elected president, and Dr. Frank K. Ainsworth, San Francisco, has been appointed a member of the State Board of Health.——Dr. Frank H. Payne, Berkley, is critically ill with typhoid fever.——Dr. Edwin von Adelung, Oakland, has been reappointed health officer.——Colton's new board of health has elected the following officers: Dr. Joseph A. Champion, president, and Dr. F. H. Pritchard, secretary.——Dr. Samuel G. Huff, San Bernardino, county physician for five years, has resigned.

ILLINOIS.

Pana Board of Health Organized.—The board of health met May 20 and elected Dr. Roscoe C. Danford, president, and Dr. Frederick J. Eberspacher, secretary.

Change at Dunning.—Dr. John R. Neely, general superintendent of the Cook County Institutions, Dunning, has resigned on account of ill health and has been succeeded by Dr. Vaclav. H. Podstata, formerly assistant at the Illinois Eastern Hospital for the Insane, Kankakee.

Addition to County Hospital.—The hospital committee of the Cook County Board has decided to erect a special building for contagious diseases to accommodate 150 patients, and a building for the care of children, to accommodate 130. These buildings are estimated to cost $125,000.

Chicago.

Personal.—Dr. G. Morgan Clarke sailed for Germany, May 26.——Dr. G. Paull Marquis has been made assistant surgeon-general of the state, with the rank of lieutenant colonel, vice Dr. Charles Adams, *transferred at his own request to the First Infantry* as major and surgeon.——Dr. Charles Adams and wife have left for New York and sail for Liverpool June 10.

A Large Class Graduated.—On May 26, the largest class ever graduated from the medical department of the University of Illinois received diplomas from the president of the University, Dr. Andrew S. Draper, who also made the address to the class. Of the 230 graduates, 25 were women. At the annual banquet more than 600 alumni were present.

Faculty Changes.—Dr. Charles S. Bacon has been elected professor of obstetrics; Dr. Andrew McDermid, associate professor of obstetrics; Dr. Frank B. Earle has been transferred from the chair of obstetrics to that of pediatrics, which he shares with Dr. W. S. Christopher, and clinical pediatrics; Dr. Maximilian Kuznik has been made adjunct professor of anatomy, and Dr. D. Lee Shaw, professor of clinical anatomy in the medical department of the University of Illinois.

May Mortality.—The total deaths during May were 2,675; 47 more than the previous month and 546 more than for May, 1902. This is equivalent to an annual death rate of 16.69 per 1,000. Pneumonia caused 646 deaths, nearly twice the number of deaths during May, 1902, from this cause; consumption, 264; violence, 175; heart diseases, 193; nervous diseases, 151; nephritis, 147, and acute intestinal diseases, 113.

Smallpox in May.—During the month 45 cases of smallpox were discovered and removed to the isolation hospital. Of these 39 never had been vaccinated; 6 had old, imperfect marks, said to be from vaccination in childhood, and 15 were unvaccinated children under 6 years of age. There were 7 deaths, and 35 cases remain in the hospital, at the close of the month, as against 47 May 31, 1902, during which month there were 57 cases removed to the hospital.

MARYLAND.

Personal.—Dr. Christian R. Scheller, Hagerstown, has been reappointed health officer of Washington County.

Hospital Still Needs Funds.—Ten thousand dollars are still needed for the Cambridge United Charities Hospital, the cornerstone of which was laid May 26. Mr. John E. Hurst of Baltimore *has been its principal benefactor, giving $15,000.*

Baltimore.

Bonds All Sold.—All the new $75,000 5 per cent. bonds issued by the University of Maryland have been sold. A new pathologic building will be erected this summer.

The Week's Mortality.—The death-rate last week was only at the rate of 12.34 per 1,000 for whites, and 14.44 for both colors. Pneumonia deaths fell to 16, those from consumption to 25. One case of smallpox was reported.

Bahama Expedition Under Way.—The expedition for scientific survey of the Bahama Islands, under the auspices of the Geographical Society of Baltimore sailed June 1. Dr. Clement A. Penrose is vice-director and surgeon and chief of the medical staff, with J. A. E. Eyster, H. P. Cole, E. B. Beasley, and T. H. Coffin of Johns Hopkins Medical School as assistants.

Bequests.—The will of Miss Louisa Catherine Belt leaves $1,000 to Dr. William Travis Howard, "in grateful appreciation of his friendship," and $5,000 in reversionary bequest to the Hospital for the Relief of Crippled and Deformed Children to endow a bed in memory of her brother. The chief portion of the estate goes to her nephew, Dr. Henry Belt, New York.

Hospital Wins Suit.—The suit against the University Hospital for $30,000 damages for alleged breach of contract for treatment of a patient was decided in favor of the hospital authorities. The patient was scalded by a hot-water bag. Testimony showed that the regents of the university, against whom the suit had been brought, had nothing to do with the hospital, it being the property of the medical faculty.

Women Graduate.—The Woman's Medical College held its twenty-first annual commencement, May 30. Of the three candidates two received degrees. Dr. Eugene F. Cordell of the board of trustees conferred the degrees. The following were elected officers of the Alumni Association: President, Dr. Hattie Frist-Emmart; vice-president, Dr. Mary A. Waters; secretary Dr. Mary N. Browne, and treasurer, Dr. Jennie N. Browne.

Resignations Recalled.—At a meeting of the Medical and Chirurgical Faculty of Maryland, May 22, the resignations, from the State Medical Examining Board of the four members, Drs. J. McPherson Scott, W. W. Wiley, Franklin B. Smith, and E. McE. VanNess, were withdrawn. This was done in response to a resolution of the faculty expressing confidence in the board and *asking the withdrawal of the resignations.* Thus was tided over what seemed to be a crisis in the affairs of the board, and the Maryland profession is to be congratulated on retaining the services of these gentlemen.

Personal.—Dr. William Osler sailed for England, May 29, with his family. He will be gone until October 1.——Drs. James Bordley, Jr., Harry E. Peterman and C. E. Holly sailed for Europe May 30.——Dr. James Bordley, Jr., has resigned the chair of ophthalmology and otology in the Woman's Medical College.——Dr. Charles E. Simon has gone to Nova Scotia for the summer.——Dr. Alexander H. Saxton has been appointed medical examiner for the state of the Royal Arcanum, to succeed the late Dr. M. B. Billingslea.

Johns Hopkins Commencement.—The Johns Hopkins Medical School graduated 19 students, 6 of whom are women. Of these 19 are from the west, 11 from the north and east, 7 from the south, 8 from Baltimore, and 1 from Canada. Selden Irwin Ramforth of Cincinnati takes first honors The 13 hospital positions, awarded to the students standing highest, will be held by the following: Selden Irwin Ramforth, Frank Hosford Watson, Robert Talbott Miller, Jr, Charles Whittier Young, Clinton Ethelbert Brush, Jr, Victor Hugo Bissett, Arthur Douglass Hirschfelder, John Timothy Geraghty, Alexander Raymond Stevens, Lewis Clyde Bixler, Willis Bein Moulton, Catherine Hutchinson Travis, Henry D Long.

MASSACHUSETTS.

Munificent Gift to Stillman Infirmary.—In addition to his original gift of $150,000 James Stillman of New York has given $50,000 to be used in the erection of a ward for the treatment of Harvard students, all with contagious diseases, entirely apart from the main infirmary building.

Vital Statistics.—Boston's death rate for the week ended May 30 again showed a decrease, reaching 16 28 per 1,000 per annum Pneumonia as a cause of death dropped to 20. Twenty six children under 1 year died and 12 under 5 years. As this was the seventh week of continuous drought it indicates the comparative healthfulness of such periods in a modern, clean city. Of infectious diseases there were reported: diphtheria, 40 cases, with 6 deaths, scarlet fever, 40 cases, with 1 death, typhoid fever, 26 cases, with 3 deaths, measles, 37 cases, with 2 deaths, and tuberculosis, 21 cases, with 29 deaths

The Shattuck Lecture.—The Shattuck lecture before the Massachusetts Medical Society this year will be given by Dr Theobald Smith on "Malaria," on June 9 Besides the usual list of excellent papers to be presented before the sessions of the society on June 9 and 10, there will be, by vote of the councilors, a discussion of the subject of "Privileged Communications,' by Dr David W Cheever and by Walter Soren, Esq, and F J Stimson, Esq. It is hoped by many that this may be the beginning of a change in the laws of Massachusetts The annual discourse this year is by Dr. Herbert L Burrell, Boston.

MICHIGAN.

New Battle Creek Sanitarium Dedicated.—On May 31, in the presence of an audience of 20,000, the new sanitarium at Battle Creek was formally dedicated

Diplomas Awarded.—At the seventh annual commencement exercises of the Saginaw Valley Medical College, Saginaw, May 14, a class of 34 was graduated

The Most Dangerous Communicable Diseases.—Meningitis was reported present in Michigan during April, at 8 places, whooping cough at 54 places; diphtheria at 56 places, typhoid fever at 78 places; scarlet fever at 138 places, measles at 148 places, smallpox at 152 places, and consumption at 187 places Meningitis was reported present at 1 place more, whooping cough at 3 places more; diphtheria at 6 places less, typhoid fever at 16 places more, scarlet fever at 9 places less; measles at 28 places more, smallpox at 17 places less, and consumption at 2 places less in April than in the preceding month

Comparative Morbidity.—For the month of April, compared with the average for April in the 10 years, 1893 1902, smallpox, whooping cough, typhoid fever and diphtheria were more than usually prevalent, and consumption, intermittent fever, erysipelas, remittent fever and meningitis were less than usually prevalent The diseases which usually cause the most sickness in Michigan at this time of the year were slightly less prevalent than usual in the April just passed Possibly this lessened prevalence was due to the higher than average temperature, and the less than average amount of ozone present during the preceding month

April Mortality of Michigan.—The total number of deaths was 2,745, or a decrease of 289 from the preceding month The death rate was lower than for the preceding month, being 13 5 per 1,000 population The mortality was also less than for April, 1902 Important causes of death were as follows: tuberculosis, 227; typhoid fever, 37; diphtheria and croup, 41; scarlet fever, 16, measles, 22; whooping cough, 39, pneumonia, 309, diarrheal diseases, under 2 years, 36, influenza, 91, cancer, 123, accidents and violence, 136, and smallpox, 3. Comparing April with the preceding month there was a decrease in mortality from other forms of tuberculosis, typhoid fever, scarlet fever and measles, and a very marked decrease from pneumonia and influenza

NEW YORK.

Personal.—Dr. Harvey R Gaylord of the state cancer laboratory is convalescing from typhoid fever.——Dr. Earl P. Lothrop has returned from the south.

State Hospital Report.—The thirty second annual report of the Buffalo State Hospital for the year ended Sept 30, 1902, shows that the population of the hospital is: men, 1,059; women, 1,237 Of those discharged 87 were recovered, 70 improved, 148 unimproved, 150 died, and 19 inebriates. The percentage of recoveries to number of new admissions, 23 15: the percentage to average population, 1.79, and the percentage to number discharged, 18 35.

Fighting Mosquitoes on Long Island.—A new motive for the extermination of mosquitoes has come to light. The manager of William C Whitney's racing stable is undertaking a crusade against mosquitoes in that vicinity, because he declares "a thoroughbred horse is all nerves and a few mosquitoes can put it out of racing condition." He is endeavoring to secure the cooperation of state, city and borough authorities, pointing out that millions of people seek rest and recreation on Coney Island beach, while just back of this spot are extensive mosquito breeding marshes. It was insisted that mosquitoes did not breed on ground that was wholly covered once or twice a day, with sea water, but in brackish water and stagnant pools of so called fresh water.

New York City.

Uniforms for Hospital Employes.—Superintendent Mabon has ordered that all employes in Bellevue and the other city hospitals shall wear distinctive uniforms.

Explosion of a Physician's Automobile.—Dr. Silas C. Blaisdell, Brooklyn, had a narrow escape from injury. He had just alighted from his automobile at his door when the automobile exploded

Ambulance Surgeon Hurt.—Dr E P. Warren, an ambulance surgeon of Bellevue Hospital, was severely, though probably not dangerously, hurt, by an electric car colliding with the ambulance, and pinning the vehicle against a pillar of the elevated railroad The ambulance driver was less severely injured, but the horse was killed and the ambulance completely demolished.

Health Department Campaigns.—The health department has received an extra appropriation of $10,000 Part is to be used in the campaign against mosquitoes and malaria; part is to assist "the typhoid section" in inspecting the water reservoirs, testing clams and oysters, and inspecting milk supplies for possible typhoid infection, and part is to be used in securing the compilation of birth certificates in order to facilitate the work of looking after the milk supplied to young infants.

PENNSYLVANIA.

Philadelphia.

Additional Milk Inspectors Needed.—By request of Dr Martin, director of the department of health, the mayor will ask councils to provide four additional milk inspectors; this will double the present force

Bequests.—By the will of the late Dr. Spencer Morris, Morgantown, W. Va., a prize of $1,000 is provided annually for the student in the University of Pennsylvania who passes the best examination for the degree of M D. A bequest of $12,500 is also given to the Medico Chirurgical College.

In Memory of Dr. Morton.—Resolutions adopted by the board of managers of the Pennsylvania Hospital in memory of Dr Thomas G. Morton, recite that his connection with the hospital began as resident physician in 1857, and that he served as attending surgeon from 1864 until his death—thirty-nine years

Typhoid and Smallpox.—Typhoid fever has not abated, there being, for the week ended May 30, 264 new cases and 27 deaths, as compared with 262 new cases and 31 deaths the previous week Smallpox seems on the increase, there being for the same period 41 new cases and 7 deaths, as compared with 18 new cases and 4 deaths the previous week.

Jewish Hospital Association.—The thirty eighth annual meeting of the Jewish Hospital Association on May 31 marked the twenty fifth anniversary of the presidency of William B Hackenburg The growth of the institution has been notable, buildings recently added are a home for incurables, one for private patients, one for nurses and an operating building.

College of Physicians to Move.—The College of Physicians will move to a lot purchased for $80,000 at Chestnut and

Twenty-second streets. It is the purpose to push the construction of a handsome building on this new site. According to a census of the physicians of the city this site is geographically very near the medical center, and is sufficiently large (130x 180 feet) for a modern building adapted to the needs of this time-honored and great institution.

Jefferson Commencement.—At the seventy-eighth annual commencement of the Jefferson Medical College, held May 28, 166 received degrees. Prof. J. von Mikulicz-Radecki of Breslau was present, and had conferred on him the degree of doctor of laws, Dr. William W. Keen acting for the faculty and Hon. William Potter for the board of trustees, in bestowing the degree. Hampton L. Carson, attorney-general of Pennsylvania, delivered the annual address to the graduates.

GENERAL.

Studies Leper Immorality Problem.—The Hawaiian Board of Health asked its superintendent of the leper settlement to investigate the conditions of immorality condemned by the U. S. commissioners on their visit last fall. He recommends that divorces be secured for those in the settlement who have wives or husbands outside and that they be allowed to marry persons within the leper colony. A number would marry who are now prevented by marriage ties with those outside.

Home for Incurables Report.—In the four months ended Dec. 31, 1902, the Honolulu Home for Incurables at Kaimuki received 34 patients. These comprised Hawaiians, Europeans, Japanese, Chinese, South Sea Islanders, Porto Ricans and negroes, and the cost of their keep per day per patient was about $1.45. In the same period there were 6 deaths in the hospital, and the average number of patients for that time was 18. The home has an endowment fund of $65,000, and the running expenses for the time covered in the report amounted to $2,803.45.

CANADA.

Union at Trinity.—Convocation for the conferring of degrees in medicine was held at Trinity University, Toronto, May 28. Provost Macklem, vice-chancellor, who presided, stated that the union of Trinity Medical College and Trinity University was now complete.

Personal.—Dr. Mikulicz, the eminent German surgeon, was the guest, last week, of Dr. Francis J. Shepherd, Montreal, and during his stay in that city performed an operation for umbilical hernia at the General Hospital before a large number of Montreal physicians and the graduating class in medicine of McGill University.——Dr. Edmund G. Weir, late house surgeon of the Toronto General Hospital, has just been successful in passing the double qualification in London, England, of M.R.C.S. and L.R.C.P.——Dr. George A. Hetherington, superintendent of the New Brunswick Asylum for the Insane, has gone to Boston on two months' leave of absence suffering from nephritis. In his absence Dr. A. Emery will discharge the duties of superintendent, and in the event of Dr. Hetherington being incapacitated from resuming his duties, will likely be appointed his successor.

Ontario Board of Health Meets.—At the regular quarterly meeting in Toronto last week, the annual report of Dr. Bryce, the medical health officer, stated that the outbreak of smallpox in Galt, which originated in a case coming from Cleveland, had totaled 142 cases, with 11 deaths. For 21 years isolation and vaccination had been the chief weapons used in combating smallpox; and in view of the fact that there is now a bill before the Ontario legislature seeking to do away with compulsory vaccination. in Ontario, Dr. Bryce considered that the statistics of those years should receive wide circulation. From 1882 to 1900 there were 135 outbreaks, 1,085 cases and 170 deaths. In 1901 there were 199 outbreaks, 2,500 cases and 12 deaths. In 1902 there were 1,800 cases. No case had yet been heard of which was officially recognized as having been taken from Ontario into a neighboring state, all going to show the efficacy of vaccination. At a later session the board took up the subject of vaccination and the bill before the legislature seeking to abolish compulsory vaccination in the province. One member expressed his belief that not more than three members of the legislature would be found to support this bill. Dr. Bryce stated that during the four months of 1903 there had been 350 deaths from scarlet fever.

FOREIGN.

Plague in Chili is reported to have come in a cargo of rice from India; 8 cases and 5 deaths have occurred at Iquique.

The Mazatlan Plague.—One new case of plague appeared recently at Mazatlan, Mexico, which was brought from Siqueiros. Quarantine was established and the great alarm caused has been allayed by the vigorous measures adopted to prevent spread.

Amputation Without Consent.—A man sued the city of Dresden for damages because his leg had been amputated without his consent in the public hospital. He claimed $6000 or a yearly pension of $300; "pain money" $50, and "mutilation money" $1,200. The court awarded him $175 and no appeal was taken by either party.

The Miners' Disease.—The epidemic among the miners of Westphalia is so serious that some mines have had to be closed and the special commission appointed by the German government to investigate recommends severe measures to stamp the disease out. They think some years will be required. The identity of the disease is not decided; it is caused by a parasite.

Railroad Hygiene.—The administration of the railroads in Prussia has created the office of confidential physician to the service, with headquarters in Berlin. He will superintend the details of the application of the principles of hygiene to the cars, stations, homes of employes, etc., preparations for aid in case of accident, etc., and will make arrangements with sanatoria for reception of employes. His duties will also include the keeping of statistics in regard to diseases, accidents and deaths in the service.

Love Potions in the Twentieth Century.—A woman at Spandau, near Berlin, was sentenced to three months' imprisonment for selling a love potion to women anxious to retain the affections of their husbands. It was found to be a mixture of linseed oil, menthol and extract of cantharides. The accused appealed the case and summoned as witnesses the women who had been her customers. The latter unanimously testified that there had been no fraud, as the potion had accomplished its purpose. The accused was acquitted.

One Victory for the Physicians in the Contract Practice Troubles.—Our German exchanges announce that, thanks to the united stand of the profession and the aid afforded by the Leipsic Verband, the sick benefit society at Mühlhausen has been obliged to conform to the wishes of its medical officers and grant their demands for more suitable remuneration. After the resignation of the medical officers and the inability of the society to secure any new physicians to take their places, the complaints of the members were so urgent that the authorities were appealed to. The latter gave the society to a certain date to provide at least six medical attendants, and when this date had passed, proceeded to reappoint the physicians who had previously resigned, acceding to their demands.

Collective Blunder Inquiry.—The *Munich Med. Wochft.* states that the official organ of the German charlatans has organized a collective inquiry to collect information in regard to blunders and barbarity on the part of qualified physicians. It appeals to have all instances of the kind known to have occurred within the last two or three years communicated to it, the editor assuming all responsibility and guaranteeing the writers against all unpleasantness. The appeal announces that "not a small proportion but the majority of physicians commit blunders." The charlatans have also banded together and proclaim a "boycott" against five of the Berlin dailies which have not upheld them, the "boycott" to go into effect next October unless the papers change their tone in the meanwhile in this respect.

LONDON LETTER.

Mr. Hutchinson's Leprosy Investigation.

Before a crowded audience at the Polyclinic Mr. Jonathan Hutchinson reported the results of his recent tour in India. Lord George Hamilton, the Secretary of State for India, presided and stated that the Indian government took a very close and personal interest in the subject. He was very glad that leprosy had diminished in India. Twelve years ago a special commission was appointed to examine the questions of the causation and prevention of leprosy, but their report was not accepted as conclusive. Mr. Hutchinson said that he went to India with a perfectly open mind, but with a strong conviction that the fish theory was the only one to explain the prevalence and disappearance of leprosy. The special commission were on the whole unfavorable to that theory because there were a certain number of lepers in asylums who denied that they had ever eaten fish. During the last ten years there had been a decided advance in general opinion as to the causation of the disease. On all sides it was stated that *leprosy* disappeared before advancing civilization and improved hygiene, but it was hardly worthy of the science of the twentieth century to conceal its ignorance under such generalities. Leprosy had receded under many conditions of advancing civilization, but this was not invariably true, as, for instance in the West Indian Islands, Spain, Portugal and Cape Colony. That the disease had nothing to do with personal cleanliness, house accommodation, or an abundant supply of food was made clear by a thousand facts. The one factor was the use of badly-preserved fish, of which he exhibited dried specimens. Leprosy was scattered all over India, and there was no place to which the fish hypothesis could not be applied. Mr. Hutchinson repeated the arguments which have recently been given in THE JOURNAL. He advocated the abolition of the salt tax as an immense boon to the community and a means of prevention of leprosy by facilitating the proper curing of fish.

Insurance Against Appendicitis.

The popular dread of appendicitis, which has now become the best-known surgical disease to the public, has resulted in a novel form of insurance. An insurance company offers to issue policies at the rate of $1.25 per annum for every $500 and to issue policies up to $2,500. By the policy the owner is guaranteed all the medical, surgical and nursing expenses up to the amount insured by an attack of appendicitis. The company points out that this premium may be largely increased in the near future as the risk of such a policy can be only indefinitely estimated.

The "Hendon Disease."

In the town of Lincoln an outbreak has for a second time occurred, apparently similar to the scarlet fever outbreak which took place in Marylebone (a London borough) and is known as the "Hendon disease." That outbreak occurred in 1885 and was investigated by Mr Power and Prof. Klein, who concluded that several cows at a dairy at Hendon suffering from a peculiar vesicular eruption on the teats and on the body, but not noticeably ill, were the source of infection Since then several similar outbreaks have been reported and traced to the same cause. In the recent Lincoln outbreak the medical officer of health has traced all the cases to one dairy in the town. All the affected persons had partaken of milk from it and the cows were suffering from a vesicular eruption on the teats and other parts. The symptoms in man are as follows: On the first day sore throat, vomiting and sometimes diarrhea, followed in many cases by a scarlatiniform rash two days later, with desquamation about a week later Most of the patients fell ill on the same day, but none of the cases were serious and no deaths have been reported. Of 40 cases notified 14 occurred in one household. In the corresponding outbreak a year ago over 100 persons were affected That appears to have been a more severe one, for there were 4 deaths All the patients drank milk from one dairy In the Marylebone outbreak a streptococcus was obtained from the vesicles on the cows. It was cultivated, and in calves produced a disease in many ways analogous to scarlet fever in man, especially in renal affection.

Vital Statistics of London.

For the week ending May 16 there were 2,615 births and 1,278 deaths. The annual death rate per 1,000, which had been 16.8, 17.3 and 15.7 in the preceding three weeks, further fell last week to 14.4. There were as many as 59 deaths from violence, of which 12 were cases of suicide, and the remaining 47 were attributed to accident or negligence. Seven of these were due to vehicles in the street, 9 to drowning, one to an anesthetic and 7 (of infants) to suffocation in bed.

Correspondence.

The Christian Hospital Swindle.

CHICAGO, June 3, 1903.

To the Editor:—The Medicolegal Committee of the Chicago Medical Society wish to make the following statement to the profession of the United States:

On Sunday, May 17, Dr. J. B. Murphy brought the Christian Hospital of Chicago to our attention. Dr. Murphy had returned from Washington that morning. In his mail he had found a letter dated May 12, offering him the presidency of the Christian Hospital. This letter was written on a letter head bearing his name as president. In the same mail were a large number of letters from physicians of the far west and southwest, some of which were dated as early as the 12th, calling his attention to the hospital and enclosing various advertising items bearing his name as president. In the main the accompanying letters are very considerate in tone, occasionally one was abusive.

On Monday the committee consulted their attorney, Mr. A. E. Dacy, of Pam, Calhoun & Glennon. They then saw Mr. Deneen, States Attorney for Cook County, and Inspector Stuart of the postoffice department. Dr. Murphy was very anxious to ask for an injunction restraining the Christian Hospital from using his name. The authorities insisted that such a course would make it impossible for them to get information. Dr. Murphy consented to wait until our committee was ready. On yesterday, June 2, Inspector Ketcham had Drs. A. C. Probert and N. E. Wood, styling himself N. News Wood, arrested for improper use of the mail. To-day, June 3, Dr. Murphy has secured an injunction in the Superior Court of Cook County, prohibiting the use of his name by the Christian Hospital or by the officers thereof.

The history of St. Luke's Hospital, of Niles, Mich., is known to most readers of THE JOURNAL. That corporation was owned by Drs. Granville and Probert. The committee has in its possession proof that Probert has served a term in the Wisconsin penitentiary. Granville has indulged in various whimsicalities. The Chicago *Record Herald* for 1899 contains a telegram from New Carlisle, Ind., announcing his arrest for bigamy, specifying five wives. It will be remembered that they made unwarranted use of the name of Dr. N. Senn of this city. In their dental department they used the name of Dr. E. C. Kinsman of Cambridge, Mass. That this was without authority is shown by affidavits, copies of which are in our possession. In 1901 Michigan became uncomfortable for this institution, and this brings us to our present story. In 1893 the Secretary of State incorporated the "Chicago Store" for general merchandise purposes. In 1901 this charter was purchased by Drs. Wood and others and the name and purpose changed so as to allow of a hospital and dispensary. In 1903 the name was changed to "The Christian Hospital." It will be noticed that when St. Lukes faded in Michigan in 1901 this one appeared here.

The reading matter and the general business policy of the institutions are identical. Nearly every name found on the Christian Hospital staff was a member of the St. Luke's staff or has appeared in some connection with St. Lukes in the past. In this connection read articles in THE JOURNAL[1] and in the *Dental Digest* exposing St. Lukes. Even the most obtuse can see that the guiding spirit of the two institutions is the same.

The postal authorities have letters from at least six physicians stating that they purchased certificates by reason of Dr. Murphy's name. We ask every man who has purchased a certificate with this understanding to do his duty as a physician and as a citizen by writing Inspector Ketcham. We have not gotten hold of any certificate as yet. Will not those physicians who have certificates send them to the Medicolegal Committee of the Chicago Medical Society?

We wish to thank Dr. Murphy for his patience in spite of a good deal of misunderstanding and some abuse; to thank Mr. Deneen and Mr. Blair, of the State Attorney's office, and Inspector Ketcham as representing the postoffice authorities.

We will keep the profession posted as to later developments. In the meanwhile we must have their co-operation.

Priority in Enterorrhaphy Methods.

ST. LOUIS, June 1, 1903.

To the Editor:—In the May 30 issue of THE JOURNAL appears a most excellent article by Dr. O. Beverly Campbell, under the title "The Single Cuff Method of Circular Enterorraphy. A New Method." My object in writing is to call attention to the fact that the method is not new, although I consider just as much credit due Dr. Campbell for his extensive experiments and for his logical conclusions as though he had been the first to publish the method.

---

[1] THE JOURNAL A. M. A., Sept 7, 1901, p. 648, and Nov. 16, 1901, p. 1329.

Die Beiträge zur klinischen Chirurgie, Bd. XIV (1895), 1-136, contains an article by R. von Frey, entitled "Ueber Technik der Darmnaht," in which he advances as original the operative procedure which Dr. Campbell has made the basis of such good work. Von Frey operated on ten dogs, of which number nine survived; while his microscopic specimens show the condition of the line of union at different periods up to two and one-half months. In a hasty survey of the literature on intestinal surgery I note that two textbook authors at least give von Frey credit for the method (both Frenchmen and very recent writers), though it would seem that his work has not become very generally known, so it is easy to see how Dr. Campbell could have overlooked it. The works to which I just referred are "La Suture Intestinale," par Terrier et Boudouin, and "Chirurgie de l' Intestin," par Jænnal, 2me edition.

As far as Dr. Campbell is concerned the method is original with him in a sense, since he evidently worked independently of any knowledge of von Frey's earlier experiments. Further, when Campbell's article reaches those who are familiar with von Frey's writings, they will be forced at least to admit that the American has done more than the German toward proving the truth of this surgical principle (as far as practice is concerned at least), since the latter worked on ten dogs alone, while the former performed 75 such experiments, to say nothing of two tests on the human subject. Willard Bartlett.

Marriages.

A. B. Howatt, M.D., to Miss Mabel Lewis, both of Chicago, May 21.

Anderson Mansfield Holmes, M.D., to Miss Azile Swann, both of Denver, April 25.

Allen Mason Thomas, M.D., to Mrs. Anna O'Neil Miner, both of New York City, June 2.

Thomas F. Spink, M.D., Washington, Ind., to Mrs. Juliet B. Brown, at Louisville, Ky., April 30.

Morton Raymond Gibbons, M.D., San Francisco, to Miss Mary Spayd Stubbs of Chicago, May 12.

Charles S. Valcour, M.D., Nashua, N. H., to Miss Florence G. Doherty of Manchester, N. H., May 23.

William King Campbell, M.D., Long Branch City, N. J., to Miss Lutie Hathaway of Long Branch, N. J., May 12.

Deaths.

Florence W. Hunt, M.D. Woman's Medical College, Chicago, 1884, whose death was noted in last week's issue, died May 27, after an abdominal section made at St. Mary's Hospital, Milwaukee. She was 45 years of age, was prominent in medical affairs for many years; was resident physician at the Cook County Insane Hospital during its stormiest days; was a member of the State Board of Health, and a member of the attending staff of St. Joseph's, and Cook County hospitals. Her illness was supposed to be appendicitis, but at the time of operation a more serious condition was disclosed. She was one of the founders and most active members of the Chicago Medical Women's Club.

George P. Cassidy, M.D. Miami Medical College, Cincinnati, 1885, died at his home in Shawneetown, Ill., May 15, from pneumonia, aged 43. He was one of the leading physicians of Shawneetown and Gallatin County. He founded the Gallatin County Medical Society, and also was a member of the Illinois State Medical Society and American Medical Association. He was a delegate to the state Medical Society, and had just returned from Chicago, where he had a chill and developed pneumonia, from which he died nine days later.

William C. Eichelberger, M.D. Rush Medical College, Chicago, 1870, a specialist on the eye and ear; a member of the American Medical Association, Vigo County (Ind.) Medical Society, of which he was once president, and the Wabash Æsculapian Society; who practiced for many years in Terre Haute, Ind., died at a sanitarium in Jackson, Tenn., after a long illness, May 18, aged 62. At a meeting of the Vigo County Medical Society, May 23, resolutions in honor of Dr. Eichelberger were adopted.

Thomas McCann, M.D. Bellevue Hospital Medical College, New York, 1886, surgeon of the Pennsylvania and Allegheny Valley railroads; surgeon to the West Pennsylvania Hospital, Pittsburg; consulting surgeon to St. Johns Hospital, Allegheny; professor of practical surgery, Western Pennsylvania Medical College; one of the most skilled surgeons of Western Pennsylvania, died at his home in East End, Pittsburg, May 9, from kidney disease, after an illness of two year's duration, aged 40.

Evan Hadley, M.D. Medical College of Indiana, Indianapolis, 1870, a member of the American Medical Association; for many years a member, and in 1888 president, of the Marion County Medical Society; for 30 years a physician of Indianapolis, died at his home in Mooresville, Ind., May 13, from organic heart disease, after a prolonged illness, aged 58. The Indianapolis Medical Society and the faculty of Dr. Hadley's alma mater adopted resolutions setting forth his excellences and deploring his loss.

Alice M. Potter, M.D. University of Buffalo, 1897, of Ithaca, N. Y., after heroic work and self-sacrifice in the recent typhoid fever epidemic, was attacked by the disease, with complications of appendicitis, endocarditis and pericarditis. Despite operation for appendicitis, she died at her home in Ithaca, May 2, aged 33. The physicians of the city, at a special meeting held May 2, adopted resolutions setting forth their appreciation of Dr. Potter's services and their loss by her death.

Edward Charles Wendt, M.D. University of Strassbourg, 1877; College of Physicians and Surgeons, New York, 1880; a member of the editorial staff of the *Medical Record* for several years, and an authority on sanitation and public health, committed suicide while temporarily insane from illness, by shooting himself, May 25, aged 45. He was residing in Paris at the time, and had been making exhaustive studies of the methods of sanitation in Europe.

George Pierce Andrews, M.D. College of Physicians and Surgeons, New York, 1862, one of the founders of Detroit Medical College, the Detroit Academy of Medicine and the Michigan State Medical Society, and until 1881 professor of theory and practice of medicine in the Detroit Medical College, died May 9 at his home in Honolulu, H. I., where he had lived for 13 years, after an illness of four days, aged 65.

Octavius A. White, M.D. Medical College of the State of South Carolina, Charleston, 1848, famous during the Civil War as a yellow fever expert, for many years a resident of New York City; a member of the New York Academy of Medicine, died at his home in New York from Bright's disease, May 25, after an illness of several weeks, aged 77.

James Clark Channell, M.D. University of Pennsylvania, Philadelphia, 1871, a member of the American Medical Association; a veteran of the Civil War; a member of the York County (Pa.) Medical Society, died at his home in Wrightsville, May 19, from pneumonia, after an illness of one week, aged 59.

John Perrier, M.D. McGill University, Montreal, 1868, professor of theory and practice of medicine, Cleveland College of Physicians and Surgeons, died from typhoid fever May 10, at his home in Cleveland, after an illness of four months, aged 60. He was a member of the American Medical Association.

Rufus Osgood Mason, M.D. College of Physicians and Surgeons, New York City, 1859, acting assistant surgeon in the Navy throughout the Civil War; a member of the New York Academy of Medicine and the Society for Psychological Research, died at his home in New York City, May 11, aged 72.

Dallas Bernhardt, M.D. College of Physicians and Surgeons, Baltimore, 1885, a member of the Huntingdon County (Pa.) Medical Society, died at his home in Three Springs, March 30, aged 46. The society, at its meeting May 14, adopted memorial resolutions regarding Dr. Bernhardt's death.

Wilson Cornelius Marden, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1896, of Pittsfield, Me., died at Mercy Hospital, Prescott, Ariz., from pulmonary tuberculosis, May 1, after an illness of four months, aged 36. He was a member of the American Medical Association.

Clinton Henry Lubbock, M.D. University of the State of Missouri, Columbia, 1880, died at his home in Alameda, Cal., from paresis, after an illness of several months, May 20, aged 42.

He served four years as member and one term as president of the local board of health.

Charles William Doyle, M.D. University of Aberdeen, Scotland, 1875, prominent alike as a citizen, physician and writer, author of "The Taming of the Jungle," died suddenly from apoplexy, at his home in Santa Cruz, Cal., May 1, aged 53.

James Melvin Sims, M.D. Marion-Sims Medical College, St. Louis, 1899, formerly of Galena, Mo., a member of the American Medical Association, died at his home in Marion, Ill., May 16, from tuberculosis, after a long illness, aged 33.

Samuel G. Dearborn, M.D: Dartmouth Medical College, Hanover, N. H., 1850, a surgeon in the Civil War, and some-time member of the New Hampshire legislature, died suddenly at his home in Nashua, May 8, aged 76.

Frank Daniel, M.D. Atlanta (Ga.) College of Physicians and Surgeons, 1902, died at his home in Moultrie, Ga., May 6, from injuries received in a collision between a motor car and a logging train, a few hours before.

Stuart Bates, M.D. Toronto (Ont.) University Medical Faculty, 1888, a member of the American Medical Association, died at his home in Virginia, Minn., May 6, from accidental poisoning by laudanum, aged 38.

Thomas Carroll Rich., M.D. Maryland University School of Medicine, Baltimore, 1869, died at Williamsport, Pa., aged 59. He was a member of the state medical society and of the American Medical Association.

Alfred Hasbrouck, M.D. College of Physicians and Surgeons, New York, 1848, for more than half a century a practitioner of Poughkeepsie, N. Y., died at his home in that city, May 9, after a short illness, aged 82.

Louis Knorr, M.D. Oglethorpe Medical College, Savannah, Ga., 1860, formerly professor of chemistry in Savannah Medical College, died suddenly, May 12, at his home in Savannah, from apoplexy, aged 78.

John W. Kirkpatrick, M.D. Rush Medical College, Chicago, 1888, president of the Eastern Iowa Medical Society, died suddenly in his office at Wyoming, Iowa, May 13, from heart disease, aged 40.

Harris Lee Paige, M.D. Jefferson Medical College, Philadelphia, 1896, formerly of New Britain, Conn., was found dead in his office in Dover, Del., April 30. His death was due to apoplexy.

Andrew Jay, M.D. Medical College of Alabama, Mobile, 1872, member of the legislature from Conecuh County, Ala., died suddenly from heart disease at his home in Evergreen, May 8, aged 52.

Hans J. Englund, M.D. Bennett Medical College, Chicago, 1888; Rush Medical College, 1895, died May 5, from pneumonia, after an illness of eight days, at his home in Cambridge, Minn., aged 46.

Joshua Chitwood, M.D. Miami Medical College, Cincinnati, 1858, a surgeon during the Civil War, died May 13, at his home in Connersville, Ind., from Bright's disease, after a long illness, aged 65.

Samuel Bridgland, M.D. Queen's University, Kingston, Ont., 1870, of Bracebridge, Ont., a member of the Ontario legislature, died, May 6, from Bright's disease, after a long illness, aged 56.

Warner F. H. O'Keefe, M.D. New York Homeopathic Medical College and Hospital, 1875, died, May 20, from Bright's disease, after an illness of two years, at his home in Pittsburg, Pa.

Howard Vance, M.D. Kentucky School of Medicine, Louisville, 1884, formerly of Ava and Le Roy, N. Y., died in Yonkers, N. Y., April 30, after an illness of four months, aged 40.

Stephen E. Rice, M.D. University of Pennsylvania, Philadelphia, 1893, died at his home in Memphis, May 6, from the effects of a self-inflicted gunshot wound of the head.

Ephraim L. Acker, M.D. University of Pennsylvania, Philadelphia, 1852, member of congress in 1870, died at his home in Allentown, Pa., May 12, after a long illness, aged 76.

Charles C. Sparklin, M.D. Rush Medical College, Chicago, 1861, died suddenly from heart disease at Goshen, Ind., where he had practiced for more than 40 years, May 5, aged 62.

Hiram J. Hartley, M.D., one of the oldest practitioners of Vigo County, Ind., died at his home near Spring Hill, May 1, from cancer, after a protracted illness, aged 79.

John Reid, M.D., 1877, health officer of Chicago after the great fire of 1871, died in London, England, May 14, from acute bronchitis, after a short illness, aged 80.

Walter Byron Sherman, M.D. Cleveland Medical College, 1870, died at his home in Eagle Cliff, Cuyahoga County, Ohio, May 19, aged 72.

Abram M. McAlpine, M.D. Columbus Medical College, 1877, of Peoria, was found dead from chronic alcoholism, April 27, aged 45.

John H. Shelton, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1882, died at his home in Tower Hill, May 13, aged 68.

George C. Synon, M.D. Rush Medical College, Chicago, 1880, died at his home in Chicago, May 21, from paralysis, aged 45.

Oliver C. Evans, M.D. Pulte Medical College, Cincinnati, 1878, died at his home in Joplin, Mo., May 5, aged 58.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ELIGIBILTY FOR MEMBERSHIP.

WHITE CASTLE, LA., May 29, 1903.

To the Editor:—Please answer the following question through THE JOURNAL: Is a homeopathic graduate, who claims he does not practice "sectarian medicine," and who is a "legally qualified and registered physician" eligible for membership in the county society, state association and American Medical Association?

WHYTE GLENDOWER OWEN.

ANS.—Each affiliated state society regulates membership in its own territory.

Medical Organization.

Reorganization Work in Arkansas.

The Arkansas State Medical Association met at Jonesboro, April 30 and May 1 and 2. The new order of things was in evidence on every hand. The actual membership had increased during the year from 190 to 697, and the increase in enthusiasm and zeal was even greater. This spirit was especially manifest in the officers and council, made up in the main from the younger members.

The program was an excellent and extensive one, and there was ample time for a full and free discussion of every paper, as the house of delegates relieved the scientific body of the consideration of all business and ethical matters. As the house of delegates was a comparatively small body, containing only about fifty members, business affairs received prompt and satisfactory attention. It was especially pleasing to find how easy it was to arrange the work of the house of delegates so as to permit the delegates to attend and take part in most of the scientific work of the general meetings.

Added interest was given to this session by the fact that an effective medical examining law had been passed by the general assembly that had just adjourned, and it was the duty of this first house of delegates to nominate members from which the governor would select the first Arkansas State Medical Examining Board. A law was also secured during the year, abolishing the system of "drumming" for practice at Hot Springs, and imposing heavy penalties on such solicitors, and all who employ them. This practice had grown to such proportions in recent years as to be a standing reproach to the profession. To the unity growing out of new methods of organization was given the credit for the enactment of all of this legislation, and it gave members some idea of what it would be possible for the profession to accomplish, when the organization was as complete as it could be made.

The council had proven so efficient that little change was made in its personnel for the coming year. It met and organized before the final adjournment of the session, the following being a list of its officers and members: E. T. Dibrell, Little Rock, chairman; Montague Fink, Helena, secretary; G. A. Warren, Imboden; M. M. Inman, Quitman; Vernon McCammon, Arkansas City; Morgan Smith, El Dorado; J. S. Coon, Nashville; C. T. Drennen, Hot Springs; J. B. Bolton, Eureka Springs, and H. D. Woods, Fayettesville.

The officers elect of the association are: President, Leonidas Kirby, Harrison; vice-presidents, J. L. Burns, Jonesboro; J. C. Cleveland, Bald Knob; J. C. Wallis, Arkadelphia; Secretary, J. P. Runyan, Little Rock; treasurer, R. C. Thompson, Pine Bluff.

Societies.

COMING MEETINGS.

Medical Society of Delaware, Dover, June 9.
Massachusetts Medical Society, Boston, June 9-10.
Michigan State Medical Society, Detroit, June 11-12.
Minnesota State Medical Society, St. Paul, June 17.
Medical Association of Montana, Helena, June 17-18.
Medical Society of New Jersey, Asbury Park, June 23-25.

Smith County (Texas) Medical Society.—At the meeting in Tyler, May 12, the following officers were elected: Dr. William S. Lacey, Troupe, president; Dr. Charles A. Smith, Tyler, vice-president, and Dr. Albert Woldert, Tyler, secretary and treasurer (re-elected).

Arundel Medical Society.—At the annual meeting in Annapolis the following officers were elected: President, Dr. H. Baldwin Gantt, Waterbury; recording secretary: Dr. B. R. Davidson, Davidsonville; corresponding secretary, Dr. Charles B. Henkel, Annapolis, and Treasurer, Dr. Frank H. Thompson, Annapolis.

Gallia County (Ohio) Medical Society.—At the May meeting the following officers were elected: President, Dr. Theodore L. Chadbourne; vice-president, Dr. Ella G. Lupton; secretary, Dr. Harry S. Allen; treasurer, Dr. S. W. Williams, and censors, Drs. Charles G. Parker, James T. Hanson, and John B. Alcorn, all of Gallipolis.

Jefferson Medical College Alumni Association.—At the annual banquet, held May 27, Dr. Thomas D. Davis of Pittsburg, esident, acted as toastmaster. Charles Emory Smith, Daniel ugh, Dr. James C. Wilson, and Dr. S. Weir Mitchell reponded to toasts. The following officers were elected for the ensuing year: President, Dr. W. Joseph Hearn, Philadelphia; a vice-president from each of the states, and one representing the Philippines; corresponding secretary, Dr. Charles S. Barnes, Philadelphia; recording secretary, Dr. Frank C. Hammond, Philadelphia; treasurer, Dr. William M. Sweet, Philadelphia, and chairman of executive committee, Dr. James T. Rugh, Philadelphia.

Chickasaw (I. T.) Medical Association.—The seventh semi-annual meeting was held in Tishomingo I. T., May 13, the president, Dr. James W. Gilbert, Roff, in the chair. The association was reorganized under the new constitution and by-laws as recommended by the American Medical Association. The following officers were elected for the ensuing year: Dr. Herbert P. Wilson, Wynnewood, president; Dr. John D. Batson, Marietta, first vice-president; Dr. F. P. Bates, Durwood, second vice-president, and Dr. J. W. Shelton, Wynnewood, secretary and treasurer. Dr. James W. Gilbert, Roff, was elected delegate to the Indian Territory Medical Association, which met at South McAlester, June 2 and 3. The eighth semi-annual meeting will be held in Ada, I. T., in November.

New York State Medical Association—First District Branch.—The nineteenth annual meeting was held, May 26, at Watertown. There were about sixty physicians present, among whom were the following: B. C. Cheeseman, Andrew J. Dick, Charles C. Kimball, J. O. Stranahan, J. N. Bassett, Edgar H. Douglas, Parker Syms, president of the Fifth District Branch of the New York State Medical Association; Dr. Frederick Holme Wiggin, president of the state association, and others. Hon. James F. Pappa, mayor of the town of Watertown, gave an address of welcome. A good program of scientific papers was carried out. Eleven new members were elected, and the following officers for the ensuing year: President, J. Orley Stranahan, Rome; vice-president, Dr. John N. Bassett, Canton, and secretary and treasurer, Dr. Edgar H. Douglas, Little Falls.

University of Maryland School of Medicine Alumni Association.—At the annual meeting and banquet, May 18, the following officers were elected: President, Dr. Henry D. Fry, Washington, D. C.; vice-presidents, Drs. George E. H. Harmon, U. S. Navy; George R. Graham and Jonah E. Gichner, Baltimore; recording secretary, Dr. Charles E. Sadtler, Baltimore; corresponding secretary, Dr. J. Fussell Martenet, Baltimore; treasurer, Dr. G. Lane Taneyhill, Baltimore, and executive committee: Drs. John I. Pennington, W. F. Skillman, J. M. Hundley, W. E. Wiegand and H. H. Biedler. The following committee to make arrangements for the centennial celebration to take place in 1907, was appointed: Drs. G. Lane Taneyhill, Eugene F. Cordell, J. Fussell Martenet, B. Merrill Hopkinson, Wilmer Brinton, John T. King, C. E. Sadtler, James H. Jarrett, John I. Pennington, Wilbur F. Skillman. The banquet hall was decorated with the university colors, and president John T. King acted as toastmaster. Toasts were responded to by Drs. George H. Hocking, John I. Pennington, J. Holmes Smith, Hon. John P. Poe, of the School of Law, C. J. Grieves, D.D.S. of the Faculty of Dentistry, and Mr. A. L. Wilkinson, president of the graduating class. There were 141 subscribers to the banquet.

AMERICAN SURGICAL ASSOCIATION.

Annual Session, held in Washington, D. C., May 12 to 14, 1903.

The President, Dr. Maurice H. Richardson, Boston, in the Chair.

President's Address.

Dr. Maurice H. Richardson, Boston, in his presidential address, spoke of the great opportunities exploratory operation offered for the study of internal diseases, especially in their earliest stages, in many instances being the only method which afforded an opportunity for exact observation. He said: "The surgeon, then, in his opportunities for observation and study, has contributed vastly to our knowledge of internal disease, especially in its early stages. His explorations demonstrate truth and control opinions; they perfect observations, and, in showing the value of deductions, teach their weight; they prove the interdependence of symptoms on lesions, and of lesions on symptoms; they demonstrate the fallacy of some inferences and the truth of others. Accumulated experience will show these things so clearly that in time the diagnosis of the clinician will approach the accuracy of scientific demonstration. In therapeutics surgery has shown what surgery can do and what it can not do, as well as what medicine can and can not do. Surgery will show still more clearly its own limitations, as well as the limitations of clinical medicine. Working together it seems not impossible that in the near future there will be no borderland between them. It will then have been demonstrated that internal diseases, even some of those now regarded as hopeless, will, by surgical or by medical therapeutics, or by both, be delegated to that class of brilliant achievement to which now belong appendicitis, gallstones, and internal hemorrhage."

Papers on Toilet of the Peritoneum.

Dr. George R. Fowler, Brooklyn, read a paper entitled "The Toilet of the Peritoneum in Appendicitis," in which he laid especial stress on the importance of avoiding infecting any areas that were not infected. When drainage is instituted, it should be by glass or smooth rubber tubes.

IN STOMACH SURGERY.

Dr. Albert Vander Veer, Albany, read a paper entitled "Operations on the Stomach, with Special Reference to the Toilet of the Peritoneum." The author felt that much of the success in the treatment of this line of cases was due to the care exercised in the toilet of the peritoneum. The abdominal contents should be handled as little as possible; traumatism should be avoided, as should also soiling the peritoneum by secretions from the mucous surfaces, which are fertile sources of infection. The importance of drainage was emphasized especially in operation on the region of the posterior wall of the stomach.

IN TUBERCULAR PERITONITIS.

Dr. A. J. Ochsner, Chicago, read a paper entitled "Toilet of the Peritoneum in Tubercular Peritonitis," in which he gave a careful résumé of the literature on the subject and his personal experience, and recommended early operation if the case was seen while the infection was still within a confined area, but if the diagnosis had not been made until late, and the patient was very weak and the infection general, he felt it was better to wait a few days until the condition becomes a little more favorable for operation.

IN PHLEBITIS.

DR. ARPAD J. GERSTER, New York, read a paper entitled "Septic Phlebitis of the Roots of the Portal Vein and Pylephlebitis, Together with Some Remarks on the So-called Peritoneal Sepsis," in which he went fully into the literature on the subject and reported four cases, giving the important diagnostic and prognostic points, and stating that while he believed the prognosis was very bad, it was not invariably hopeless, but that early diagnosis and prompt operation are the only safeguards.

DRS. R. H. HARTE, Philadelphia, and S. H. WEEKS, Portland, Me., also read papers on the toilet of the Peritoneum.

AFTER GUNSHOT WOUNDS.

DR. GEORGE TULLY VAUGHAN, Washington, *D. C.*, read a paper entitled "Toilet of the Peritoneum in Gun-shot Wounds of the Stomach and Intestines," in which he emphasized the necessity for drainage and thorough cleansing of the abdominal contents in all cases.

IN DIFFUSE PERITONITIS.

DR. JOSEPH BLAKE, New York, read a paper entitled "The Treatment *of* the *Peritoneum* in Spreading and Diffuse Peritonitis," in which he divided the purulent forms of peritonitis into three classes: 1. Cases in which there is a localized collection of pus with limiting adhesions: 2. Cases with spreading peritonitis, in which there is no limitation of the process by adhesions or gravitation, but in which the limits are ascertainable. 3. Cases of general peritonitis, in which no parts of the peritoneum, possibly excepting the lesser sac, can be demonstrated as free from the invasion. The treatment which has given the best results in his experience is as follows: 1. Early operation. 2. Lavage of the peritoneum with large quantities of saline solution. 3. Closing of the peritoneal cavity without drainage, unless the latter is absolutely indicated by the presence of non-absorbable amounts of necrotic material. Appended to the paper was the report of a large number of cases.

DISCUSSION.

DR. JOHN C. MUNRO, Boston, discussed Dr. Gerster's paper, and said he considered the chill a very important symptom, although a very irregular one. In his opinion the sensorium is not clouded, the appetite is ravenous, although there may be tremendous emaciation, and in many cases jaundice is present. He believes that if cases could be gotten early enough they could often be satisfactorily treated. The subphrenic abscesses are more apt to be secondary, following liver abscesses, although they may come from retroperitoneal lymphangitis.

Operations for Trigeminal Neuralgia.

DR. ROBERT ABBE, New York, read a paper on a simplified and improved operation for trigeminal neuralgia, by intracranial neurectomy, with *interposition of rubber tissue, and without* resection of the gasserian ganglion. After having operated for many years *by the usual intracranial method, with one* death from shock, he had adopted a modified method in eight cases *during the past seven years, which he regarded as a* distinct improvement. Satisfied from study of the nerves removed *extensively* anterior to the base of the skull, that the disease is, in almost all cases, an inflammation of the nerves *affected in the bony channels* adjacent to the antrum and teeth, he regards the temporary cure by nerve resection within the skull as proving that ganglion resection is uncalled for. The recurrence being unquestionably due to reunion, he prevents that by interposing a small piece of sterile rubber tissue between the ganglion and the outlets of the second and third branches, which are all he ever resects. This method has, in eight cases, given the same excellent results as in ganglion resection.

Experiments on rubber tissue showed that it always remains sterile and is never changed in texture. Therefore it remains as a permanent barrier to reunion. The complete operation consists in: Ligation of the external carotid in the neck; a straight incision from just behind the middle of the zygomatic arch; upward and slightly forward in the temporal fossa; splitting the temporal muscle and scraping it widely from the bone; enlarging to one and a half inches a small trephine opening, and lifting the brain and dura mater from the middle fossa; exposing and resecting a half inch of the second and third branches in front of the gasserian ganglion; spreading a rubber tissue strip an inch and a half long over the openings and pressing it down on the bone till all bleeding stops; letting the ganglion settle down *on* the tissue and closing the wound.

DISCUSSION.

DR. GEORGE R. FOWLER, Brooklyn, commented on the uncertainty of the author's method, reporting a case in which it worked very well, and another one where it did not work at all, although he was able to explain the cause of the failure in the latter case. He did not think one could depend entirely on *the ligature of the* external carotid as a means of preliminary hemostasis.

DR. GEORGE E. *BREWER*, New York, mentioned a case in which he had employed the methods with satisfactory results. His experience in ligature of the external carotid has been that the hemorrhage is venous, and hard to control, seeming to come in most cases from a tributary of the cavernous sinus.

DR. ABBE claimed to have satisfied himself that the disease was in the nerve and not in the ganglion. He referred to the existence of spots of inflammation along the nerve sheath, which he thought were probably the original sites of the neuralgia, from which the disease worked its way back to the ganglion, if not into it.

Ulcer of the Bladder.

DR. GEORGE E. ARMSTRONG, Montreal, Canada, read a paper entitled "Single Ulcer of the Urinary Bladder, Non-tuberculous and Non-Malignant, with Report of Cases," in which he reported the case of a man 21 years of age, without venereal *history and of temperate habits, in whom the attack came on* suddenly without known cause, accompanied by the following symptoms: 1. *Pain at the end of the penis about the corona* and on the dorsum, just before micturition and generally so severe as to necessitate the administration of morphia. 2. Frequent micturition, and 3, loss of expulsive power. The patient died eight months after the onset, operation having been performed in the meantime, and the autopsy showed acute miliary tuberculosis of both lungs, the left adrenal, spleen, left ureter, kidneys and bladder. The second case occurred in a boy 12 years of age and was cured by injections of silver nitrate. He went fully into the literature on the subject and stated that he believed the three chief causes of single ulcer of the bladder to be *infection*, thrombosis and syphilis. The chief symptoms are pain, frequency of micturition and *presence of small quantities of blood in the urine.* The prognosis is good, if recognized early, and he believed *operation gave as good chances of relief as for ulcer in the* stomach.

DISCUSSION.

DR. WILLIAM L. ESTES, Bethlehem, Pa., added another case to those reported in the paper. The case was one of a man fifty years old, who was operated on with the idea that he had septic peritonitis, but his condition was found to be due to an ulcer of the bladder resembling very closely an ulcer of the stomach. The patient made a good recovery.

DR. H. R. WHARTON, Philadelphia, narrated a case of *enchondroma* of the spinal column, which developed a year after a strain while lifting. The tumor was excised and *the patient* recovered.

(To be continued.)

AMERICAN GYNECOLOGICAL SOCIETY.

Twenty-eighth Annual Meeting, held in Washington, D. C., May 12 to 14, 1903.

The President, Dr. Joseph E. Janvrin, in the Chair.

(Continued from page 1531.)

Repetition of Cesarean Section on the Same Patient.

DR. CHARLES M. GREEN, Boston, after a brief summary of the experience of the Boston Lying-In Hospital with repeated cesarean sections, raised the question whether it is justifiable in performing cesarean section for either an absolute or an

The Differential Diagnosis.

Dr. George E. Brewer, New York, claimed that much of the information obtained in reference to this disease has been due to the conditions found at the time of operation. He divided the subject into (1) calculus disease, (2) inflammatory disease, and (3) new growths, and called especial attention to the pain in impacted gallstone. The presence of the gall bladder near the median line, as well as its congenital absence, was referred to, and the cause of the pain in gall-bladder disease was believed to be due to inflammatory conditions, although it may be due to pressure and spasm. The most characteristic symptom of cholelithiasis was considered to be the pain, while the most conspicuous symptoms of stone in the common duct were mentioned as jaundice, pain and fever. In the author's opinion, inflammation of the gall bladder is present in most cases coming under the surgeon's hands, but a tumor of the gall bladder was rarely found. The three chief symptoms of obstruction were given as (1) pain, (2) tumor and (3) jaundice, and the fact that gallstones are rarely found in young persons, say under 20, was alluded to.

The Etiology and Pathology of Gallstone.

Dr. C. A. Herter, New York, considered the chief constituents of gallstones to be cholesterin and bilirubin. He showed a table giving the results in the formation of cholesterin after injections into the gall bladder. After mentioning that cholesterin is increased in pneumonia, he stated that the quantity of this substance in the blood was very little in relation to the quantity in the bile. As to bacteria in gallstones, reference was made to the work of Welch, who found the *Streptococcus pyogenes*, or the colon bacillus, while a bacterial nidus was found in one-half of the stones. In reference to the artificial production of stone the principal obstacle to its accomplishment was believed to be the flow of bile. Inflammation of the gall bladder superinduced by ascites and unaccompanied by any infection, is not itself sufficient to give rise to a very marked increase in the percentage of cholesterin in the bile. The author stated that gallstones may be produced experimentally by the introduction of bacteria, although he felt there was considerable evidence that we are going a little too far in assuming that all cases of gallstone are due to bacteria and nothing else.

Stomach Complications.

Prof. C. A. Ewald, Berlin, read a paper on "The Diseases of the Gall Bladder and Bile Ducts, with Especial Reference to Diseases of the Stomach and Intestines," in which he stated that gallstones arise from a catarrhal condition of the mucosa, often occurring in members of the same family, showing a predisposition. He raised a question as to gallstones causing pain, stating that the colic may be due to contractions or inflammations, with or without stone. He looked on the pain as being a very variable factor, and as sometimes originating from the transverse colon. The importance of chemical and microscopic examinations of the gastric contents was spoken of, and the statement made that hyperchlorhydria was frequently present and disappeared with the attack. He stated that gall-bladder colic was variable, irregular and frequently occurred at night, and called attention to the similarity between gastric crises and gallstone colic. The importance of differentiation between gall-bladder colic and acute pancreatic disease was briefly alluded to, and it was claimed that a tumor of the gall bladder was more frequently absent than present. The stones may perforate into the colon, and the contents of the intestines may be vomited, while infection of the bile passages from carcinoma occurs fairly frequently. The author believes that 95 per cent. of all cases of carcinoma are complicated with cholelithiasis. He made the statement that carcinoma is more frequent in women than in men, the percentage being about four to one, and called attention to the fact that it was unknown why stone should sometimes cause ulceration and at other times carcinoma. In his opinion carcinoma of the biliary passages is less frequent in women than in men, and expressed himself as being in favor of medical treatment in gall-bladder cases being employed first. He advised the ordinary known remedies during an attack of acute inflammation, but where they were unusually severe he recommended prompt operation, as well as in recurrent attack. The possible fatal result of a parenchymatous hemorrhage was alluded to, and also the unfortunate results which sometimes follow operation.

A Study of 534 Operations on the Gall Bladder and Bile Ducts.

Dr. William J. Mayo, Rochester, Minn., commenced his paper with the statement that in Nature's defense against infection within the abdominal cavity there are three weak situations, the fallopian tube, the appendix and the gall bladder, of which the first to gain an accepted surgical position was the infective lesions of the tube. While he considered that the appendix had reached an assured place in surgery, he considered that the gall bladder had been slow to receive that attention from the medical public which its importance deserved. He compared the similarity between the appendix and the gall bladder, and explained why perforation and sudden death are less frequent in diseases of the gall bladder than the appendix. He showed the relative preponderance of the two conditions according to the age of life of the patient, and also the relative frequency of operations on the appendix, gall bladder, ovaries and tubes and stomach. The 534 operations on the gall bladder and bile passages which formed the basis of this paper were performed on 518 patients, with 19 deaths, a mortality of 3.5 per cent. Of the total number, 510 were for gallstone disease, with a mortality of 3 per cent. Considering stones in the gall bladder as uncomplicated, there were 208 cases with 2 deaths, a mortality of less than 1 per cent. While, in his opinion, the colic is the standard of measure in the diagnosis of gallstones, yet it is but a small part of the clinical picture, and is readily diagnosticated. While it is known that the large majority of adults with gallstones never suffer, it is equally true that these stones only slumber, with the possibility of a painful awakening. The ideal operation, which is complete closure of the gall-bladder incision, has been successful in many of these cases of slumbering stone, while the hope of the patient that the stones will pass down and out through the common duct frequently materializes; usually, according to the author, there were more behind, and he has never operated on a patient who has passed calculi without finding more in the gall bladder. Commenting on the safety of operations on the common duct, he claimed that the mortality depended more on the condition of the patient than any difficulties in the technic, and gave Dr. Robson the credit for the great improvement in the technic. Eighteen times has he met with chronic pancreatitis in connection with gallstone disease, and in four of them cholecyst-duodenostomy was successfully performed, while in the remaining twelve no special treatment was adopted. The average stay in the hospital was slightly less than three weeks, the attempt being to remove all of the stones at the primary operation. Malignant disease of the gall bladder and bile duct was met twenty-four times, in some of which the exact origin could not be determined. As the presence of gallstones only occurred in 15 per cent. of secondary cancers of the gall bladder, and in over 80 per cent. of primary cancers, it was concluded that they were the chief etiologic factors in the production of malignant disease.

Surgical Treatment of Obstruction of the Common Bile Duct by Stone or Tumor.

Prof. Hans Kehr, Halberstadt, looked on the pressure of bile as the chief factor in forcing stones through the duct. He did not think one could determine at the time of the colic whether the stones were large or small, nor whether they passed through the ductus choledochus or not. Acute obstructions of the duct are rare, and sometimes a spontaneous cure may result, but he attached but little importance to the passage of a stone, because there were probably others. If pancreatic trouble be associated with stone in the gall bladder he advised treating this at the same time, but was not in favor of breaking up the stone, as all the broken parts might not pass through. He believed that drainage was more quickly performed than suturing, and felt that in colotomy, with sutures, many stones were left behind. In his opinion the success of the operation depended on the pathologic conditions present. He urged the use of a free abdominal incision, and a generous quantity of gauze packing, believing they played a most important part in the results obtained. While he believed that the treatment of obstruction of the ductus choledochus properly belonged to internal medicine, he advised against waiting more than three months before operating. He did not think an incision into the hepatic duct was very often necessary, but attached great importance to the after treatment following operation.

DISCUSSION.

Dr. **Frank Billings**, Chicago, commented on the fact that surgeons had, in the greater part of the operations done in the last few years, so enlightened us in the diagnosis of these conditions that it can be much more readily made than formerly, but in spite of this, considered it was absolutely impossible to make a rational diagnosis in many cases. The most prominent symptom referred to by present writers is pain, usually in the region of the gall bladder apparatus, not always severe, nor always colicky in character. Points of tenderness may be present without any pain, especially in cases whose abdominal walls are not too thick. Within one year two patients have called on the author, both of whom had been operated on for cystic gallstones without the stones having been found, the condition in each case being that of gastric crises, due to locomotor ataxia. The fact that cases of appendicitis were often operated on for gallstone, and that floating kidney and inflamed appendix may refer pain to the gall bladder region, was briefly noted, and the statement made that in one sense gallstones are harmless, and do not present symptoms sufficient to make a diagnosis until there is infection of the gall bladder region. In the Doctor's opinion, by the time we are able to make a diagnosis of gallstone the case is no longer a medical disease but a surgical one. He emphasized very strongly the fact that if once a diagnosis is made and one can elicit the information that gallstones have repeatedly occurred in the past an operation is indicated and should be performed at once. However he was in favor beforehand of trying to get rid of the infection by proper food, drink, respiratory exercise, and in the case of women by adjustment of the dress, but if these failed he urged operation at once.

Dr. **George Dock**, Ann Arbor, Mich., commented on the fact that nothing but carelessness or ignorance in many cases prevented patients from being sent to the surgeon, and he believed this was largely due to their not knowing the beneficial results to be obtained by surgical treatment. Cases of gallstone disease resemble appendicitis and renal colic, but a careful examination will in most cases clear up the diagnosis satisfactorily. In his opinion, more has been learned from the surgeon than from the pathologist in these cases, largely owing to the fact that many of them do not come to autopsy at all, so that the pathologist does not have an opportunity of studying them.

Dr. **Henry Sewall**, after stating that the bile is a continuous secretion, with rhythmic accelerations due to contraction of the larger bile ducts, said it would be interesting to consider how the bile got into the gall bladder during the intervals between its outpourings into the intestine, which he proceeded briefly to explain. He said it was granted on all sides that the dangers of gallstone disease depend on bacterial invasion of the gall bladder and gall ducts, and that the formation of gallstones may presuppose such invasion. Commenting on the entrance of germs from the intestine, the sphincter muscle of the duct must form a useful barrier, but germs must be constantly penetrating the common duct, and once in the duct they must find ready access to the gall bladder, except for the possible filtering power of the Heisterian valve in the cystic duct. He supposed it was well known that all factors restricting the free outflowing of bile (dress, habits of eating, etc.) predisposed to gallstones, and also if the bile, when secreted by the liver, is already infected, it can not serve as a cleansing fluid. In his opinion, a prominent or principal use of the gall bladder is to serve as a flush tank for the common and cystic duct, and it maybe suspected that atrophy or extirpation of the gall bladder might predispose to cholangitis.

Dr. **E. G. Janeway**, New York, urged that the character of the food taken should be under the control of the physician.

Prof. **B. S. A. Moynihan**, Leeds, England, stated that although operations on the common duct used to be considered extremely serious, they were not losing at the present time more than 3 or 4 per cent., and he attributed this improvement to the kind of incision which is being used, through which one is able to see the gall bladder and pull out through the wound about one third of the liver. He expressed considerable satisfaction from this little detail in the operation, and claimed to be able to operate on the common duct in twenty to thirty minutes. One is being driven often and oftener to an inspection of the gall bladder, making it necessary to employ an incision which would permit of this.

(To be continued.)

FOURTEENTH INTERNATIONAL MEDICAL CONGRESS.

Held at Madrid, Spain, April 23-30, 1903.

(Continued from page 1525.)

Section on Medicine.

The second session was completely monopolized by long communications from physicians belonging to the Latin races, dealing largely with diseases endemic in Southern Europe, and the discussions were carried into the other sessions. Maragliano, Genoa, Italy, the honorary president of the section, called attention to the fact that the congress was losing its true character as an international gathering for the rapid and concise interchange of views, but his words were without effect. Drs. Espina and Castellino, Naples, reviewed the current opinions in regard to the "Pathogenesis of Cardiac Arrhythmia."

Several of the papers presented in the third session have already been mentioned. Dr. Sanudo, Madrid, discussed the subject of the "Diagnosis of Myocarditis," but presented no new ideas.

Radiography in Biliary Lithiasis.

Drs. Gasteln and Yogue, Madrid, reported that they had radiographed a large number of cases, subsequently submitting their findings to the control of operation or autopsy. They found that radiography does not permit of differentiation between stones in the gall bladder and dense pericystic adhesions or hydatid cysts. Thus it fails just where its aid is most needed.

Rheumatism.

Dr. Ibanez, Valencia, asserted that rheumatism is not of microbic nature, but due to faulty metabolism with accumulation of uric acid. All the forms of rheumatism and gout are manifestations of the same disease.

In the fourth session Dr. Princos, Saragossa, reviewed the present standpoint with regard to pleurisies.

Salocreol.

Dr. Guezda, Berlin, said that the new drug was a synthesis of the various phenols of creosote and salicylic acids to form an ester. In von Leyden's clinic it has proven of great value in the treatment of rheumatic joints, of scrofulous glands and of the adenopathies of measles and scarlatinal anginas. It is applied with a brush or rubbed in as the degree of tenderness of the parts dictates, and thus applied appears in the urine in a few hours. Its chief value is in reducing or abolishing the tendency to suppuration of the acute and chronic glandular swellings, and has established its efficacy as the best drug in erysipelas.

Therapeutic Action of Air Baths and Sun Baths.

Dr. Singer, Berlin, described the physiologic action of this treatment, which is both tonic and sedative. It is applicable in a large number of conditions, but chiefly in neurasthenia.

Dr. Mariani, Madrid, spoke on the "Curability of Tuberculosis," and Dr. Iglesias on what he called "Madrid Fever." Dr. Mariani also discussed "Hysteria as an Agent in the Production of Aortic Lesions."

He further called attention to the value of "Blood Enemas in Chlorosis." He stated that he had experimented for 20 years in the treatment of anemias by this method. It is ineffectual in symptomatic anemias, but in chloranemias of the most advanced type, which have resisted every other form of treatment, it gives invariably good results. The blood of a sheep, aseptically secured, fresh each day, and defibrinated, is injected in amounts of 300 c.c. There are never any toxic or intestinal disturbances, but the enemas are followed by a rapid improvement in all the symptoms, paralleled by the tendency to normal of the blood count. Moreover, the cure is lasting. The manner of absorption of the blood is still unexplained.

Rectal Injections of Antistreptococcus Serum.

Sir Dyce Duckworth, London, described a typical case of acute infectious endocarditis, with fever, chills, petechial rash and joint symptoms, which yielded to this form of treatment after every other method had proven fruitless.

Etiology of Acute Rheumatism.

This communication by Drs. Poynton and Paine, London, will be reviewed later.

Dr. Larand, Carlsbad, emphasized its great importance. He is inclined to accept the conclusions presented. Dr. Singer, Vienna, stated that the so-called diplococcus referred to was identical with a streptococcus which he had isolated two years ago, but had found that it was not specific. Dr. Blumenthal, Berlin, said that agglutination and immunization occurred only with the specific form of streptococcus originally employed, and not with others. There was no one streptococcus of rheumatism.

Dr. Moragas, Madrid, discussed the treatment of hemoptysis.

Mucomembranous Colitis and Appendicitis.

Dr. F. Bernard, Plombières, has collected 1,100 cases of mucomembranous colitis, of which 76, or 6.9 per cent., presented unmistakable evidence of appendicitis, while many others had probable symptoms. In 12 cases removal of the appendix was followed by cure of the colitis. Ordinarily, the syndrome of appendicitis is present, but not marked, and the symptom-complex might be characterized as "appendicism." Pathologically it is reasonable to assume that the mucosa of the appendix participates in the disease present in the cecum and colon; the coexistence of enterolithiasis is also probably an etiologic factor in the appendicitis.

Pseudo Uremia in Urinary Lithiasis.

Dr. Galland Gleize, Vittel, said that he had observed cases of "gravel" of long standing, in which there occurred, with more or less suddenness, attacks which in many points simulated a true uremia. Examination of the urine, however, gave no support to the theory of a nephritis. The attacks were marked by a predominance of gastrointestinal symptoms; they usually lasted much longer than is customary in uremic attacks and terminated abruptly. The termination was marked by an abundant elimination of sand and calculi. He concludes that the phenomenon is simply a form of nephritic colic of gastrointestinal type.

Dr. Melcior, Levida, recommended the treatment of cholera with quinin.

At the conclusion of the session telegrams expressing gratitude were sent to the men who have contributed so much to the elucidation of the etiology of malarial infection, Laveran, Baccelli, Manson, Grassi, Koch and Ross.

(To be continued.)

PHILADELPHIA ACADEMY OF SURGERY.

Special Meeting, held May 11, 1903.

The president, Dr. Richard H. Harte, in the Chair.

Mayo on Stomach Surgery.

Dr. William J. Mayo, Rochester, Minn., read a paper entitled "A Review of 303 Operations on the Stomach and First Portion of the Duodenum," 286 of which were taken from the records of St. Mary's Hospital, Rochester, Minn., and 17 from the Minnesota State Hospital for the Insane at Rochester and St. Peter. The average age was 42, 42 per cent. being males and 58 per cent. females. There were 26 cases of duodenal ulcer with two deaths. Lesions in the first portion of the duodenum can not be easily differentiated from lesions in the stomach which are due to the same causes.

He divided lesions in the first portion of the duodenum into two groups, first, those caused by ulcer; and, second, those associated with the gall-bladder disease. Of the ulcers limited to the duodenum, there was 1 acute perforating, 2 chronic perforating, 5 active and 3 cicatricial contractions with obstructive symptoms. Two deaths occurred, one from pneumonia and the other from exhaustion following gastroenterostomy.

DISEASES OF THE STOMACH CLASSIFIED.

Dr. Mayo divided the gastric affection into two classes:

1. Gastric ulcer and associated causes of serious disturbance.
2. Cancer of the stomach.

Out of the 303 cases reported in this paper 277 involved the stomach, with 28 deaths, or 10.1 per cent.; 168 of these cases were in the benign group with 11 deaths. These cases included all the non-malignant obstructions or conditions calling for operation for gastric pain, with or without acute exacerbation. In the majority of the cases the perverted stomach secretion seemed to be the most important cause, which is shown by the almost constant association of excessive secretions with gastric ulcer. Also in that part of the duodenum not protected by alkaline juices the same ulcers have occurred after jejunostomy has been performed for the purpose of drainage. Drainage to relieve the excessive amount of secretion and thus produce healing of the ulcer is of great importance.

GASTRIC ULCER CLASSIFIED.

The following classification of gastric ulcer was made:

1. Round ulcer: (*a*) acute; (*b*) chronic. They have the definite feature that there is but little thickening about the base of the ulcer.
2. Mucous erosions, a condition which must be accepted with caution.
3. Chronic ulcer with thickened base and usually irregular in form.
4. Benign obstruction without regard to cause, although usually of benign origin.

The last two classes are the ones which most frequently call for operation, chronic ulcer being usually found in adults and is more frequent in females. Spasm of the pylorus was thought to be one of the most important causes of the retention of excessive gastric secretion.

There were 109 cases of cancer of the stomach, with 17 deaths, or 15.6 per cent. Late diagnosis and cachexia make the report of this group rather discouraging; most of the operations were of a palliative character. Early exploratory incision in suspected cases was recommended, and all the vascular and lymphatic connections with the diseased area should be removed. He then gave a full description of the method he employed in doing the operation.

Difficulty of Diagnosis.

Dr. Albert Vander Veer, Albany, referred to the difficulty of diagnosing conditions in the lower third of the stomach and the upper third of the duodenum. He felt that many of the cases were left too long solely under the treatment of the medical man, and when the clinical history and examination of the patient do not reveal clearly the conditions present he recommended exploratory operation.

Murphy Button Versus Suture.

Mr. B. G. A. Moynihan, Leeds, England, felt that the operation of pyloroplasty could be practically abandoned, he having done the operation three times, and in only one of the three cases did it prove satisfactory. He did not feel that the operation was in any particular as satisfactory as the operation of gastroenterostomy, stating that he had operated on seventy-five cases by the latter method with only one death. He stated that he had not used the Murphy button in the last sixty-five cases, as he believed the simple suture was preferable, but stated that in the employment of the Murphy button in the first of his cases, he had noticed that it destroyed a considerable portion of the mucous membrane around the union, which he considered of very great importance, and which he had been doing in all his operations. By the method which he has employed the section of the stomach and the section of the jejunum where the anastomosis is to be made are each grasped in a pair of forceps and brought outside of the abdomen, and the continuous suture applied. Malignant disease of the stomach he believed came principally through the lymphatic system, and in the operation therefor, he believed that first the greater curvature and then the lesser curvature should be removed. Duodenal ulcer he believed to be rarely primary. Gastric ulcer is so frequently multiple that he did not believe excision thereof to be practicable, as future trouble may result from a remaining undiscovered ulcer.

Importance of Early Treatment.

Dr. J. B. Murphy, Chicago, said the great majority of all cases of carcinoma occur in the pyloric end of the stomach, and as the first set of glands to become involved by gravity are the lymphatic glands, any operation which is expected to produce permanent results must look to the removal of these glands, early operation being imperative. About 10 per cent. of all cases of gastric carcinoma occur in the cardiac end and are practically unamenable to treatment. The surgeon usually sees the cases of gastric disease numerically in the following order: (1) gastric carcinoma; (2) gastric ulcer; (3) pyloric stenosis, and (4) pyloric retention. As the gastric carcinoma is usually a sequence of the other conditions, he felt that in order to obtain the best results by operative treatment, the order in which these cases were seen should be the reverse He believed that in order for the operation of pylorectomy to attain the best possible results, it was necessary that it should be done early. He referred to the fact that the cases of gastroptosis are treated erroneously by the medical man by washing out the stomach and reducing the amount of food, on the theory that the condition is due to a weakening of the wall of the stomach, whereas, as has been definitely demonstrated by Dr. Mayo, it is due to a mechanical condition at the pylorus. He felt that the all-important factor in the operation was to secure permanent drainage of the most dependent portion of the stomach, and the only operation which had been used a sufficient length of time to justify the statement that it was the best he felt was gastroenterostomy. He felt that if pyloroplasty was going to be of benefit to the patients it must be done early, in order to avoid ulceration and changes in the gastric secretions which are apt to lead on to malignant disease. He also expressed the opinion that so soon as it became demonstrated to the physician that surgical operations were safe and afforded great relief, the cases would be sent to the surgeon much earlier

Dr. J M T Finney, Baltimore, believed that the main question was thorough drainage, and any method that would produce this result he felt would be satisfactory. He advocated early exploratory operation under cocain.

Prof. von Mikulicz Radecki, Breslau, Germany, spoke in German on the subject.

On motion a unanimous vote of thanks was tendered those who had spoken

---

AMERICAN PROCTOLOGIC SOCIETY.

Fifth Annual Meeting, held in New Orleans, May 5 and 6, 1903.

The President, Dr. S. T. Earle, Baltimore, in the Chair.

After the transaction of preliminary business, President Earle delivered an able address on "The Qualifications for Membership in the American Protologic Society."

The papers presented at this meeting were of unusual interest.

X-Ray Therapy in Ano-Rectal Diseases.

Dr. J. Rawson Pennington dwelt in this paper on the importance and efficiency of this agent in the treatment of pruritis ani where the cause is local.

The society asked Dr. Pennington to continue his searches in *x*-ray therapy in rectal diseases.

Tubercular Ulceration of the Rectum and Anus.

Dr. L. H. Adler, Philadelphia, stated that tuberculosis is now recognized as the cause of a number of conditions about the anus and rectum, the pathology of which was formerly obscure. The disease may be a primary process, but in the majority of instances it is secondary to similar changes in other organs. It may involve any portion of the rectum or the skin about the same; its most frequent site, in the author's experience, however, is at the mucocutaneous junction. The affection is always due to the tubercle bacillus. Any plan of treatment, to be of benefit, must, in a large measure, be directed to the general constitutional condition; and for this purpose, pure air, forced feeding and all the hygienic and medicinal measures should be adopted as are employed in general tuberculosis. The local treatment has for its main objects the destruction of the tubercle bacilli and the establishment of a healthy reparative process. The Paquelin or the galvano cautery, chemical caustics, such as chlorid of zinc, nitric acid and acid nitrate of mercury, the curette and the *x*-ray, have been employed for these purposes and with varying results.

Dr. Leon Straus, St. Louis, reported cases of primary tuberculosis of the rectum.

Atony of the Rectum and Anal Sphincters; Its Etiology, Pathology, Diagnosis and Treatment.

Dr. William Bodenhamer, New York, said the condition is most commonly met in delicate women of a lax muscular fiber, and in those whose sedentary occupations lead to a lack of regularity of function. The first desideratum in treatment is a regular habit respecting a daily evacuation of the rectum. "This may be aided and often attained by simple means, such as the injection of half a pint of cold water into the rectum at the regular time of going to stool; cold being tonic, stimulant and astringent and acts somewhat similarly to nux vomica by exciting the sensibility and contractility of the organ; but it should be discontinued as soon as the object of its use has been attained. In the more obstinate cases, however, the chief remedies should be nux vomica, alone or combined with some other ingredients, together with the employment of rectal injections composed of powerful astringents and tonic substances, with the intention of inducing contraction, corrugation and condensation of the relaxed and weak muscular fibers of the rectum, by which they become shorter and firmer, and thus aid in diminishing the morbid organ to its normal dimensions and tone."

Obstipation.

Dr. John L. Jelks, Memphis, Tenn., read a paper entitled "Obstipation, Its Causes, Effects, Diagnosis and Treatment." He stated: "Obstipation is the term used by proctologists to denote mechanical obstruction of the bowel, and is preferred to the generic term of which obstipation is one variety." He classed the causative factors as follows: 1, Extravisceral; 2, perivisceral; 3, visceral; 4, intravisceral. One of the chief facts which the author wished to forcibly express is that other factors may and do cause obstipation or obstructive constipation, and a careful discrimination should be made before an operation is performed on a supposed obstructing rectal valve.

Dr. B. Merrill Ricketts, Cincinnati, exhibited an instrument, and Dr. George T. Cooke, Indianapolis, discussed the subject of "Hemorrhoids." These elicited considerable discussion, and Dr. Ricketts was instructed to make further report on the use of the angiotribe in the treatment of hemorrhoids. The discussion disclosed the approval of various methods of treatment of hemorrhoids, but showed that none of them are ideal.

The Treatment of Anal and Rectal Diseases Without General Anesthesia.

Dr. William L Dickinson, Saginaw, Mich., said: "The treatment of anal and rectal diseases has been so long associated with that of general anesthesia that when a patient presents himself and we have made an examination we unconsciously begin to solve the mental problem of how he will take the anesthetic and the number of days he will be confined to the house after the operation. The time-honored treatment of anal fissure by dilation, under chloroform, was both effective and speedy, but we can accomplish the same results in a little longer time by the use of cocain or eucain. Superficial fistulæ, ischio-rectal abscesses, external hemorrhoids and many cases of internal hemorrhoids can be operated on under filtration just as well as under general anesthesia. We owe it to our patients and also to ourselves to keep patients from going to the irregular practitioner, for, as regular, educated physicians, we ought to be able to cope with all diseases of the rectum, in an intelligent manner, and thus give entire satisfaction to our patients. Our students should be taught that the greater number of our patients seek our advice and aid for ailments that respond readily to office treatment that can be given without general anesthesia."

Molluscum of the Rectum.

Probably the most interesting paper of the meeting was that of a report on "A Unique Case; Molluscum Fibrosum of the Rectum in a Patient, the Subject of the Typical Skin Lesion," by Dr. A. Bennett Cooke, Nashville. He stated: "The feature of the case which justifies the adjective 'unique' is not the skin disease nor the occurrence of the multiple fibroid tumors in the rectum, but rather the association of the two conditions in the same individual and the further fact that the mucous and cutaneous tumors are identical in structure." He described the patient as emaciated, sallow, nervous and despondent; at least a dozen calls to the stool in twenty-four hours; sphincters relaxed and perianal integument excoriated from the irritating discharges; anal canal patulous, in spite of numerous successive abrasions. The proctoscope revealed the rectum almost completely filled with polypoid tumors, many of them ulcerated and bathed in a muco-purulent blood-stained secretion of exceedingly offensive odor. The growths began in the lowest rectal chamber, varying in size from a bird shot to an almond; the largest were uniformly pedunculated, those intermediate in size had sessile attachments, and the smallest appeared as mere elevations under the mucous membrane, well bedded. It was found that the lesions extended well into the sigmoid colon, smaller in size, and were attended by less inflammation of the mucosa. Beginning below the tumors were removed by torsion with the forceps and by biting them off with a curette against the sharp end of the proctoscope. The hemorrhoid was rather free, so that it was possible to remove only a small number at a sitting. The operation was repeated from time to time during a period of three weeks, when the bowel, as high as could be seen, was clear of all but the smallest tumors. Sixty of the growths were removed; no anesthetic was employed."

Dr. Cooke appended a report from the *Pathologist*, which demonstrated the identity of the skin and rectal lesions. The production was considered a valuable contribution to proctologic literature.

Election of Officers.

The society elected the following officers for the ensuing year: President, Dr. William M. Beach, Pittsburg; vice-president, Dr. Leon Straus, St. Louis; secretary-treasurer, Dr. A. Bennett Cooke, Nashville.

The next meeting will be in Atlantic City, June 7 and 8, 1904.

AMERICAN ACADEMY OF MEDICINE.

Twenty-eighth Annual Meeting, held in Washington, D. C., May 11 and 12, 1903.

(Continued from page 1529.)

The President, Dr. Charles McIntire, Easton, Pa., in the Chair.

Gonorrhea as a Social Danger.

The scientific session was opened on the second day by a paper with this title by Dr. Prince A. Morrow, New York. A distinction should be recognized between cases in which the disease is contracted through voluntary exposure to contagion under immoral conditions and those in which contagion is conveyed through innocent relations. Modern acquisitions to knowledge, especially of gonorrhea in women, have established on a scientific basis the magnified importance of gonorrhea as a social peril. The extent and degree of this danger, Dr. Morrow claims, are not sufficiently appreciated by the profession.

The paper considered the principal modes in which gonorrhea of the innocent may be manifest as a result of marital infection, and detailed the remedies, emphasizing the protective duty devolving on the physician.

The paper was discussed by Drs. Gerrish, Benedict, Bulkley and Risley.

Electives in Anatomy.

The "Symposium On Required and Elective Studies in the Medical Course" was then opened by Dr. F. H. Gerrish, Portland. A knowledge of the structure of the entire body is fundamentally important, the author stated, for the medical man, even if his work is in a limited field, for he can not be the best kind of a specialist unless he is an all-round practitioner at the start, and it is injudicious to encourage the undergraduate to undertake additional anatomic work. Electives, he claimed, are appropriate for those who have attained the doctorate, and wish to broaden and deepen their knowledge in particular lines.

The Teaching of Pathology in the Medical Curriculum.

Dr. William H. Welch, Baltimore, in this paper, considered the period in the medical course for teaching pathology; the apportionment of laboratory work and didactic teaching; recitations and conferences; the extent to which various branches of pathologic teaching may be combined in single course; the character of examinations, and the methods adopted at the Johns Hopkins University. The student should have a good training in microscopic anatomy and histology and a training in physiology in order to enable him to take up with any profit the study of pathology, and he should keep in touch with pathology during the remaining years of his course.

It has been found advantageous to separate the more immediate and direct practical applications of pathology to clinical medicine from the course in the second year and to transmit it to the third and fourth years of the course. The plan is to begin with bacteriology and keep it in close relation with histology or pathology. Didactic lectures are not dispensed with, but go in as they are needed in connection with the course. Disturbance of circulation, disturbance of normal heat, etc., which do not admit of demonstration very readily, are taken up in their proper connection in a series of lectures in connection with the diseases of circulation.

Regarding the matter of electives, Dr. Welch regards the statement of Dr. Bowditch as the most comprehensive; the first essential being to fix on a minimum in the subject which must be taught, that is, every student must have this minimum knowledge of pathology. The difficulty comes in determining the minimum. That, however, is the plan in operation in Johns Hopkins University. The amount of teaching has been lessened and courses established which are elective in pathologic anatomy, histology and the different departments. Dr. Welch is therefore very much in favor of endorsing the system of electives so far as is possible along the lines elaborated by Dr. Bowditch, so far as he knows them: Determining the minimum requirement in a given subject and then supplying special courses along the different lines, the advantage of this being the well-recognized advantage of optional interchange and also the distinct advantage of taking up one aspect with very great thoroughness, none of which is opposed to Dr. Gerrish's conception that, after all, the main purpose of the medical school is to train medical practitioners. This plan Dr. Welch regards as really conducive to that end.

Internal Medicine: To What Extent Required or Elective in the Medical Course?

Dr. Sherman G. Bonney, Denver, gave a few general fundamental considerations relative to the present professional and educational status and discussed some of the recent advances in the methods and character of medical instruction. He gave the definition and scope of the elective system in American medical colleges and the objection to its too general application. The relation of internal medicine to the elective system of instruction is regarded as unique and distinctive.

Required and Elective Dermatology.

Dr. L. Duncan Bulkley, New York, in this paper, said that diseases of the skin are notoriously among those about which the least is known by the general medical profession. While many of the colleges have special instructors in this branch, it has not hitherto been taught so as to efficiently inform graduating students. Proper knowledge of dermatology is often most important in general practice, especially in the case of syphilis and the exanthemata, while many of the ordinary diseases of the skin are exceedingly important in their bearing on the health and usefulness of the patient. In order to properly understand the subject of dermatology, which is essentially a clinical branch, Dr. Bulkley claims that there should also be a good knowledge of microscopy and bacteriology. Those contemplating special practice in dermatology should be encouraged to take special courses as electives during the last two years.

A Theory and a Condition as Illustrated by Ophthalmology.

DR. EDWARD JACKSON, Denver, read this paper. He stated that the time-honored theory of one course of undergraduate study, with gradual development years after graduation toward special from general practice, does not now meet the requirements of ophthalmology. Special training should begin in the course preparatory to medicine to attain the best practical results, and a certain part of ophthalmology should enter into the training of every medical student Certain other things, however, should be taught early in their student career to those who expect to practice ophthalmology. A wise recognition of electives in the medical curriculum may prevent the complete separation of certain specialties from the general practice of medicine and surgery.

DISCUSSION.

DR. BOWDITCH agreed with Dr. Gerrish that the general practitioner has not yet gone by, stating that he would be with us for many years. He also believes with Dr. Gerrish that the elective system affords the best means for training general practitioners. *In the Harvard Medical School* all the required instruction is condensed into three years.

DR. EDWARD JACKSON spoke of the educational value of the electives. He believes that whether a man is in general practice or in any line of practice, his first object as a practitioner of medicine should be that of original investigation.

How the Modern Physician Can Influence in Decreasing the Birth Rate.

DR. ROLAND G. CURTIN, Philadelphia, in this paper, pointed out that this decrease could be brought about, first, by increasing the expenses of the family in high charges, expensive nursing and extensive outfits; and second, by discouraging advice.

The New Officers.

The following officers were elected: President, Dr. John B. Roberts, Philadelphia; vice-presidents, Drs. T. D. Davis, Pittsburgh, Pa.; James H. McBride, Pasadena, Cal.; J. T. Searcy, Tuscaloosa, Ala.; S. A. Knopf, New York; secretary, Dr. Charles McIntire, Easton, Pa.; treasurer, Dr. E. M. Green, Easton, Pa.; assistant secretary, Dr. Alex R. Craig, Columbia, Pa.

Atlantic City was named as the next place of meeting.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen *especially in every-day practice.* Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Diabetes.

A. Robin, *according to an abstract in the Courier of Med.*, recommends in the treatment of diabetes, that grains 15 (1.00) each of antipyrin and sodium bicarbonate be taken one hour before dinner and supper. The amount of sugar excreted daily will, under this treatment, rapidly be reduced to 50 per cent. of its original amount. This treatment should be continued for three days, when it should be replaced by the bihydrochlorid of quinin in ten-grain doses (.60) on rising, which should be repeated for six days, alternating with the following:

℞.	Sodii arsenatis	gr. 3/4	05
	Aq. destil.	℥i	30

M. Sig.: One teaspoonful before each meal.

Lithia carbonate may also be given in three-grain (.20) doses three times a day before lunch, or sodium citrate in two and a half grain (.15) doses before each meal. Sodium tartrate *may* be ordered instead of the above salts, in doses of grains six (.40) each.

In cases where nerve sedatives are indicated give the following:

℞.	Ext. bellad.	gr. 3/40	005
	Ext. opii	gr. 1/6	01
	Ext. valerianæ	gr. iiss	15

M. Ft. pilula No. i. Sig.: Three to ten such pills daily.

Coryza.

Dr. G. Bjorkman, in *Merck's Archives*, recommends the following combinations in the treatment of coryza in the early stages:

℞.	Quin. muriatis		
	Camphoræ, āā	gr. 1/4	015
	Ext. belladon. rad. flu.	gtt. 1/8	008

M. Ft. capsulæ No. i. Sig.: One such capsule every fifteen minutes until relieved; or:

℞.	Ext. suprarenalis aq.	gr. xv-xlv	1.-3
	Aq. destil. steril.	ʒiiss	10

M. Sig.: To be applied to the nasal mucous membranes several times a day with a brush; or:

℞.	Menthol	gr. xxx	2
	Spts. chloroformi	℥ss	15

M. Sig.: Twelve drops to be dropped into the palms of the hands and rubbed until most of the chloroform has evaporated. The hands should then be formed into a mask and the vapors inhaled for five or ten minutes, every half hour; or:

℞.	Ext. hamamelidis aq.	℥i	30
	Sol. acidi borici (1 per cent.)	℥i	30

Sig: A small amount added to a teaspoonful of water to be snuffed into the nose repeatedly; or:

℞.	Zinci sozoiodol	gr. xxx	2	
	Menthol	gr. ivss		25
	Sacch. lact.	℥i	30	

M. Sig.: To be insufflated into each naris several times a day.

The Dose of Codein.

According to Fraenkel, in *Munch. Med. Woch.*, the dose of codein should be larger than the dose ordinarily given in order to obtain the full physiologic effect of that preparation. It is twenty times less powerful than morphin. It should be given in doses ranging from 2/3 gr. (.01) to 3/4 gr. (.05), repeated three or four times a day. The single maximum dose may reach grain 1½ (.09) and the maximum daily dose 4½ grains (.28). In administering it to children the following daily dose may be allowed: Age four years, gr. 1/6 (.01); age six years, gr. 1/3 (.02); age eight years, gr. 2/3 (.04); age twelve years, gr. 1¼ (.075).

Scabies.

The following ointment, which is similar to that formerly employed by Kaposi, is recommended in the treatment of scabies:

℞.	Naphthol	ʒiv	15	
	Saponis viridis	℥iss	45	
	Pulv. cretæ	gr. xl	2	65
	Adipis	℥viii	240	

M. Ft. unguentum. Sig.: Apply locally, dust with starch powder and wrap in a linen cloth.

The following combination is recommended by Local Handbook of Ther.:

℞.	Naphthol		
	Sulphuris precip., āā	℥i	30
	Adipis	℥viii	240

M. Sig.: Apply locally after scrubbing the parts well with soap and water.

Constipation.

Gant, in the *N. Y. Med. Jour.*, states that he has discarded rugs entirely in the treatment of constipation, and by employing the following outline of treatment his results are positive in all cases: Massage is essential in the cure of constipation, attention being directed not only to the large intestines but to the liver, small intestine and rectum. It improves the circulation, loosens any adhesions present and increases peristalsis. Faradism is of great value, applying the positive pole over the spine or within the rectum and moving the negative over the abdomen and liver.

Enematas of warm soapsuds are sometimes necessary to relieve an overloaded colon. The patient is given the following instructions:

1. Go to stool at the same hour each day and make a strong effort to move the bowels, whether successful or not.
2. Correct errors in diet; be regular about the meals and masticate the food thoroughly.
3. Eat sufficient fruit and drink an abundance of water, especially on rising.
4. Take a cold bath every morning, to be followed by thorough friction.
5. Regular indulgence in outdoor exercise and gymnastics, *paying special attention to those movements which tend to* develop the abdominal muscles.
6. Change from a sedentary to a more active occupation if it is deemed necessary.

Seborrhea.

Seborrhea, *according to* Shoemaker *in Med. Bul.*, requires constitutional as well as local treatment. If gastrointestinal disturbances are present the bowels must be kept properly active and bitter tonics administered. Iron should be given when anemia or chlorosis is present. Seborrhea is most frequent on the scalp; however, the hair should not be cut short but some bland oil should be applied to remove the crusts. The use of tobacco must be avoided and oatmeal, fish, pastry and fried foods cut from the articles of diet. The patient may eat baked potatoes, eggs, beefsteak, lamb chops, baked or stewed fruits and roast beef once a day. He should eat no supper.

The following should be given internally:

℞.	Podophyllotoxin		
	Ext. belladonnæ		
	Ext. nucis vom., āā	gr. 1/10	006
	Ext. taraxaci	gr. i	06
	Pepsini puri	gr. ss	03

M. Ft. pil. No. i. Sig.: One such pill four times a day.

The following ointment should be applied locally after the crusts have been removed:

℞.	Chloralis hydratis.	gr. xv-xxx	1.-2	
	Olei eucalypti	m. v		30
	Magnesii carb.			
	Zinci carb., āā	ʒss	2	
	Ung. aq. rosæ	℥i	30	

M. Ft. unguentum. Sig.: Apply locally.

According to the author the chloral is soothing, antipruritic, and aids in *contracting the follicles.*

Sedative in Neurasthenia.

The following combination, recommended by Lewis in *Amer. Med.*, is of service in quieting the nervous symptoms of neurasthenics:

℞.	Potassii *bromidi*	ʒiv	15
	Tinct. ferri chloridi	ʒiii	12
	Glycerini	ʒii	8
	Aq. q. s. ad	℥iv	120

M. Sig.: One teaspoonful to be taken in half a glass of water and repeated as often as necessary in order to decrease the pains and produce sleep.

Migraine.

In order to lessen the suffering from an acute attack of migraine the first essential, according to the *Med. News*, is absolute rest in a darkened room. Heat should be applied locally to the feet and a mustard poultice to the back of the neck, and the head well wrapped in a shawl. Tea and coffee should be avoided, and if the patient has a tendency to a gouty diathesis colchicum should be given, or if rheumatic the salicylates or aspirin, alternating with sodium bromid. The eyes should be examined and the teeth cared for. If an attack occurs during menstruation a sitz bath should be taken and the following given internally:

℞.	Spts. chloroformi		
	Spts. ammon. arom.		
	Tinct. card. co., āā	ʒii	8
	Liq. ammon. acet. q. s. ad	℥iii	90

M. Sig.: Two teaspoonfuls and repeat in two hours if necessary.

Citrophen, according to the author, acts admirably in some of these cases.

When nausea and vomiting are present the following mixture is suggested:

℞.	Tinct. zingiberis	ʒi	4	
	Tinct. capsici	m. xxxvi	2	40
	Syr. zingiberis	ʒiv	15	
	Aq. menth. pip. q. s. ad	℥iii	90	

M. Sig.: Two teaspoonfuls and repeat as necessary.

In the gouty form the following is valuable to give relief:

℞.	Antipyrini	ʒi	4
	Sod. salicylatis	ʒiss	6
	Aq. cinnamomi q. s. ad	℥ii	60

M. One teaspoonful every hour until relieved.

Or, according to Merck, the following:

℞.	Quin. valerinatis	gr. xv	1	
	Ext. colchici			
	Ext. digitalis, āā	*gr. iv*		25
	Ext. aconiti	gr. ii		12

M. Ft. pil. No. x. Sig.: One at noon and night.

If neuralgic in character the following is recommended:

℞.	Antipyrini		
	Butyl-chloral hydratis, āā	ʒii	8
	Syr. *zingiberis*	℥ii	60
	Aquæ	℥i	30

M. Sig.: One teaspoonful every two to four hours.

Decubitus.

The following in *Merck's Archives* is recommended by Bjorkman *in the treatment of bedsores: The points of pressure* should be properly protected by pads and air cushions. Absolute cleanliness is imperative. The sheets should be removed frequently and aired once or twice a day; remnants from meals should never be permitted to remain in the bed. When dejecta come in contact with the patient, the parts should be thoroughly cleansed antiseptically and astringent lotions applied. The following lotion serves well as a preventive measure:

℞.	Aq. hamamel. dest.		
	Spts. vini, āā	℥iii	90

Sig.: Apply locally.

The author recommends light massage as a stimulant to the sluggish circulation. If sloughing should occur one of the following combinations may be used:

℞.	Nosophen	ʒi	4
	Lanolini	℥i	30

M. Ft. ung. Sig.: Apply locally; or:

℞.	Potass. sozoiodol	ʒiiss	10
	Lanolini		
	Liq. petrolati, āā	℥iss	45

M. Ft. ung. Sig.: Apply locally.

Medicolegal.

Rules for Weighing Expert Testimony.—The Supreme Court of Nebraska, in Modern Brotherhood of America vs. Cummings, holds not erroneous an instruction in which the jury were told that in weighing expert testimony the same test was to be applied in weighing other testimony, and which continued as follows: "In weighing expert testimony, it is important that you should consider whether the fact on which the opinion of the witness is given has been satisfactorily proven—whether the expert is in any way biased and prejudiced, as shown by the evidence. You should also consider what experience, skill and learning in his profession the expert is shown to have. In weighing expert testimony offered for the purpose of contradicting the testimony of other witnesses who have positively stated facts claimed by them to have been within their personal knowledge, you should not fail to distinguish between those inferences or conclusions of the expert which are shown to be only probable and generally true, and which have their exceptions, and those other inferences and conclusions, if any, which are necessary and invariable, and which have no exceptions. You should also consider whether the opinion of the expert is speculative, theoretical, and states only the belief of the witness, while yet some different opinion, conclusion or inference may be drawn from the same facts." As to the question of whether the arm of the party by whom the action was brought was broken or not, which was in dispute, the jury were told that it was not for the expert to determine, but was alone for them to determine from all the testimony in the case.

Hastening Death by Inflicting Wound on Diseased Person.—Briefly summed up, the Court of Criminal Appeals of Texas says that the physicians' testimony in Gardner vs State, a homicide case, showed that the deceased was in the last stages of Bright's disease, his elbow broken by a pistol shot; chloroform administered for the purpose of surgical operation, the kidneys, paralyzed by means of the chloroform, and failing to perform their functions, threw uric acid back on the system by poisoning the blood, thereby causing death The physicians also testified, in this connection, that this was the proper treatment under the peculiar circumstances, and that the operation was a necessity Whether the life of the deceased could have been saved by some other means than the operation, or whether there was negligence in this connection or improper treatment in not investigating the condition of the deceased's kidneys prior to the operation, does not seem to have entered into the testimony The accused, who fired the shot, asked an instruction to the effect that if the deceased was shot, but the wound thereby inflicted was not necessarily fatal, and the wounded party was suffering from or afflicted with a disease not connected with or superinduced by the shot, and died therefrom, then the accused should be acquitted altogether of any grade of homicide. This charge was refused, and the court holds that it was properly so. It holds that if the deceased was suffering from a disease or a wound, and the accused's shot hastened the death of the deceased, he would be guilty of homicide. If the deceased would have shortly died from Bright's disease, and it was an incurable malady, yet if the accused's shot assisted in bringing about the death, he would be guilty of the homicide. An accused can not speculate as to how long his victim may live with an incurable malady when he inflicts a shot or a wound that hastens the death or the action of the fatal disease.

What Physician May Recover When Own Child Injured.—The Court of Civil Appeals of Texas says, in St. Louis Southwestern Railway Company of Texas vs Gregory, that physical or mental pain suffered by an infant, by reason of personal injury or wrong inflicted by the negligence of another, is not an element of damages which the parent is entitled to recover, but the right to recover damages for such pain is personally of the infant If, however, the pain which the child suffers is such as to incapacitate him for services to his parent, the latter will be entitled to recover damages, not for the pain, but as compensation for the loss of services caused by the pain to the child Though an infant be injured, there is no right to recover by the parent therefore, unless the injury be such as to cause loss of services, or require, at the hands of the parent, some expense or outlay that otherwise would not have been made necessary. Medical services, and all necessary expenses of the care and treatment of a child whose injury or sickness is caused by the negligent or wrongful act of another, are elements of damages arising from such negligence It is not necessary that the parent engage a stranger to administer medical treatment to the child, if the parent himself is a physician competent to perform such medical services If he performs such services, he is entitled to recover from the wrongdoer a reasonable compensation therefore, for such wrongdoer has made it necessary because of his wrongful act. But the recovery by the parent should not exceed the value of the services performed. He can not recover for the loss of patronage as a practicing physician while detained at home on account of the sickness of either his wife or child. Such damages are too remote. Nor is the anxiety and mental anguish suffered by him and his wife, or either of them, by reason of the child's sickness, proper elements of damages.

Power to Quarantine—Requiring Notice by Physician.—The Supreme Court of Iowa says, in the case of State vs. Kirby, that it is unquestionably true that the preservation of the public health is of paramount importance to the state at large, as well as to local communities, and that the state, in the exercise of its police powers, may confer on the state and local boards of health whatever powers are deemed necessary for the preservation of the general health of a community or of the state. It may, perhaps, be conceded that, even in the absence of express statutory authority so to do, the authorities of a local community would have inherent or implied power to adopt such rules and regulations as were reasonably necessary for the preservation of the public health of such community; but, whenever the state has expressly conferred such power, it must be exercised as provided in the grant. The policy of the law of this, as well as most of the other states, has been to confer great power on those boards; and it may be conceded, so far as the exercise of those powers is concerned, a liberal construction should be given to the rules and regulations adopted by such board. But they must not unreasonably interfere with the liberty, property and business of the citizen. And whether such regulations are reasonable, impartial and consistent with the state policy is a question for the court. While the law seeks the welfare of the greater number, and says that individual liberty and property must yield for the time being thereto, it has prescribed the preliminary steps necessary to deprive the citizen of these constitutional rights, and it is but just and in accord with settled legal principles that the courts require a strict adherence to the statute in matters of this kind. Chapter 59 of the Acts of the Twenty-fourth General Assembly provided that, "upon written notice given by any physician that smallpox . . . exists in any place, it shall be the duty of the mayor . . . to establish quarantine." Section 2568 of the Iowa Code says that "the quarantine authorized . . . in case of infectious or contagious diseases may be declared or terminated by the mayor . . . upon written notice given by any practicing physician of the existence of such disease" The local rules under which the local board of health acted in this case in undertaking to quarantine the party charged with disobeying its order were adopted in 1894, and the court thinks did require a written notice as provided by the statute; but whether this was so or not the statute required it when the rules were adopted, and, what was of more importance, it was required when the attempt was made to quarantine this party. No such written notice, however, had been given by any physician; and the court thinks the board was, for this reason, without authority to restrain the party. It is not necessary for the preservation of the public health, the court says, that the mayor be allowed to shut a person up in his own house, or in a pesthouse, on the mere suggestion of any one who may be unduly alarmed over appearances. Every town now has a competent physician for its health officer, and, in case of his temporary absence or inability to act, other competent physicians may easily be obtained for an examination and the written report required by the statute. The suggestion that this party had consented to this quarantine leads the court to further say this, that he might have waived a formal notice thereof might be conceded, but surely it would not be contended that he could be convicted of a violation of the quarantine statute simply because he had agreed to remain secluded from his fellows for a given length of time. Had he done this, he might be guilty of a breach of contract, but nothing more.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Philadelphia Medical Journal.

May 23

1 The Third and Final Report of a Case of Presystolic Mitral Murmur, Complicating Pregnancy, Etc., with Exhibition of Specimen, Showing Triple Valvular Lesion, viz., Mitral Stenosis, Tricuspid Stenosis and Aortic Stenosis. James Tyson.

2 *The Present Treatment of Puerperal Septic Infection. Edward P. Davis.
3 *Decreasing Fecundity: Its Causes and Results. Scott P. Child.
4 Malnutrition. Theodore J. Elterich.
5 *A Fatal Case of Anthracosis, with Autopsy. Thomas S. Githens.
6 The Local Use of Cocain in the Nose. W. G. B. Harland.

2. **Puerperal Septic Infection.**—Davis insists on the importance of prophylaxis, asepsis during obstetric cases, following every possible precaution. Among the methods of treatment which have proven of value he includes thorough cleansing of the uterus and vagina; cauterization of ulcers with carbolic acid and iodin; sponging out the vagina with cotton dipped in a 1 per cent. lysol solution or mercury bichlorid, 1 in 4000, and thorough exploration of the uterus with a blunt-edged curette to bring away necrosed material, but avoiding wounding of the tissue; the use of prolonged irrigations with lysol or creolin, 1 per cent., or normal salt solution at about 100 F. or more. If bleeding is exhausting it is well to pack the uterus moderately with gauze containing 10 per cent. of iodoform. No mercury bichlorid should be introduced within the uterus under any circumstances. The vagina should be lightly tamponed with dry bichlorid gauze left there for forty-eight hours, followed by thorough irrigation of the uterus and vagina with 1 per cent. lysol solution. No further douching should be practiced. Other measures mentioned as of decided value are applications of cold to the abdomen over the uterus with counter-irritation by turpentine stupes, prompt emptying of the intestines, the use of tonics and stimulating drugs, especially strychnia and ergot, liberal feeding, good nursing, the use of normal salt solution, either by the bowel or hypodermically, etc. He objects to hysterectomy in pelvic or abdominal abscess, and thinks it justifiable only where the infected placenta can not be removed. Such cases are of the rarest occurrence. If, on opening the abdomen, the fallopian tubes are found distended with pus, their removal is justifiable. The methods which must at present be considered as experimental are the use of streptococcic serum, the use of nucleids to produce increased leucocytosis, Credé's silver ointment applications, injection of formalin as recently recommended, hysterectomy and the ligating and dissecting out of the infected and thrombosed veins. He believes in hysterectomy during labor in infected cases, and mentions cases where recovery followed Porro's operation. Among the injurious methods he includes drugs to reduce temperature, too much anxiety to stimulate the heart by the use of digitalis, etc., the tendency to check purgation which Nature sets up, and repeated intrauterine manipulations. He advises the poor and those of little means to go to hospitals for confinement, where private rooms at prices available should be provided.

3. **Decreasing Fecundity.**—Child reviews the statistics, accepting apparently the prevalent opinions as to the actual decrease of fecundity of American women, and attributes it to the social customs, prevention of conception and gonorrhea and syphilis, especially the former, which he thinks is an important cause. He also mentions criminal abortion, which he seems to consider frequent.

5. **Anthracosis.**—Githens reports a case in which a diagnosis of tuberculosis was made, but the lungs showed pronounced anthracosis without the presence of any tuberculosis. Chemically, the pigment was about one-fifth of the lungs by weight, and 6.23 per cent. of the pigment was ash. This seemed to indicate that the anthracosis was due to hard coal and that the patient had worked as a miner before taking up his later occupation as barber. The points of interest were the youthfulness of the patient, the history of syphilitic infection five years previously and that the anthracosis was the direct cause of death. He remarks on the paucity of literature of the condition. With the exception of one article by Osler in 1875, he finds no mention of the disease in the United States, and he can learn of no cases from physicians in coal-mining districts.

Medical Record, New York.

May 23.

7 *Some Unusual Cases of Appendicitis. Robert F. Weir.
8 *On a Case of Complete Fibrous Obstruction (Congenital?) of Both Superior and Inferior Venæ Cavæ in a Young Man of Eighteen Years—First Recorded Case. Alfred Meyer.
9 *Total Respiratory Failure from Ether—Artificial Respiration for Over Four Hours; Recovery. H. H. Everett.

7. **Appendicitis.**—Several unusual cases of appendicitis are described by Weir, including one of internal intestinal strangulation from an elongated inflamed appendix with a clubbed termination attached to the side of the lower lumbar vertebræ; one of strangulated hernia with gangrenous appendix; one of tumor of the cecal wall following removal of the appendix; one of very short appendix, one-half inch long, which was productive of several sharp attacks. When it was found its lumen was nearly obliterated and its walls very much thickened and sclerosed. It was at first taken to be merely a remnant of the appendix, but close examination showed it to be complete. There was also a case of appendicitis with general peritonitis operated on, with also repeated venous infusions of normal salt solution and recovery. Weir follows the suggestion of Crile to limit the amount to 1000 or 1250 c.c. and add 10 to 15 minims of a 1-1000 solution of adrenalin chlorid, and also 5 per cent. of sterilized glucose or .03 per cent. sodium saccharate. The results have been excellent. Lastly, he reports a case of cancer of the appendix which was operated on, and the patient has remained well for over three years. He remarks that with the exception of this case and that of the short appendix, all occurred within the last year.

8. **Obstruction of the Venae Cavae.**—In the case reported by Meyer, both the superior and inferior venæ cavæ were obliterated and the entire return venous circulation was provided for by the dilated vena azygos major. He reviews the literature of such cases to a certain extent and holds that the cause of the obstruction here was obscure, with no evidence of specific disease.

9. **Ether Asphyxia.**—In the case reported by Everett the patient was being operated on for appendicitis in which gangrene and adhesions were found. Respiration finally ceased, and for four hours artificial respiration and adrenalin chlorid, strychnia, etc., were employed. The patient made a good recovery, which Everett attributes largely to the adrenalin.

12 *Notes on Blood Pressure in Man. (Continued.) S. S. Goldwater.
13 The Circulation in Puerperal Eclampsia. Douglas H. Stewart.
14 Some Interesting Phenomena of Specific Immune Sera. Arthur P. Hitchens.

10. **Fracture of the Spine.**—Three cases of fracture of the spine, one including gunshot wound, are reported by Williams. He attributes the fatal result in one of his cases of fracture of the lumbar vertebræ to drainage after treatment, and holds that drainage in such a wound is not only useless, but attended with danger. In two of his cases he thinks that he might possibly have succeeded in myelorrhaphy according to the method of Stewart and Harte, but the wound would have had to be lower in the cord. He thinks that hereafter we will operate earlier in cases of spinal fracture and oftener in severer cases, knowing that even if the cord is completely crushed the destroyed zone may be removed and the ends approximated. Keen's rule, that after an accident, if the knee-jerk is absent and remains so, operation is contraindicated, should hold good no longer. Absence of deep reflexes should be the most urgent reason to perform exploration.

12. **Blood Pressure.**—Goldwater, in this portion of his article, discusses the influence of posture, which has the effect of producing a lessening of pressure to an average of 15 mm.; muscular exertion, which causes a rise, and baths, which have little effect on a healthy person, according to his experience, though cold baths decrease the heart's frequency and strengthen its force. A rising blood pressure thus produced should be contraindicated in cases of threatening hemorrhage. Other things which alter the blood pressure are massage and perspiration, the former increasing, the latter reducing. Local pressure alterations produced by aneurism are also noted by arteriosclerosis, which may be accompanied with extremely low as well as extremely high tension, according to the condition of the heart, whether weakened or not, and by nephritis where the

value of the tonometer is most apparent. Often the high tension may be the first indication of renal complications. The effects of the nitrites are also mentioned and observations reported in two cases. The fall seemed to be slight, the patients being dispensary patients and not entirely under control. Better results might be obtained in lowering the tension by these drugs in hospital practice. It can not be maintained that as yet any material result has been achieved by the study of the relations between blood pressure and valvular disease. The tension is high in proportion to the degree of compensation hypertrophy and low in uncompensated lesions. The depression of the blood pressure in mental disorders is remarked on, and also the pressure during fever. One distinct service that he mentions which the blood-pressure apparatus has done is to prove that arterial tension may be exceedingly low during the early stage of high fever, when the pulse is full and bounding; relaxation of the arterial walls is, no doubt, the cause. The suggestion is made whether having in the future better control of the circulatory apparatus during this period might not be of some value. In convalescence the clinician must not be surprised to see abnormalities.

15 *A Study of 534 Operations upon the Gall Bladder and Bile Passages, with Tabulated Report of 517 Operated Cases. William J. Mayo
16 *The Germicidal Action of Alcohol. Charles Harrington and Harold Walker.
17 Report of Five Cases of Fracture of the Hip in Children. H. M. Chase, Jr
18 A Glass Urethral Irrigator. David D. Scannell.

15. **Gall-Bladder Operation.**—In 534 operations on 519 patients operated on by Mayo there were 19 deaths, or a mortality of 3.5 per cent.; 510 were for gall-stone disease, with a mortality of 3 per cent. In uncomplicated cases there was less than 1 per cent. mortality, but in complicated cases, including stone in the ducts, infections with and without stone, and malignant disease the mortality rose to 5 per cent. This is significant and indicates the importance of early operation. Mayo calls attention to the possibilities of even latent gallstone disease, and remarks that operation in uncomplicated cases is very simple. Cholecystostomy not only effectually cures the condition, but by permanently elevating the fundus brings the cystic duct to the bottom of the cavity and furnishes better drainage for the future. The "ideal" operation for closure of the gall-bladder incision has been successful in cases where slumbering gallstones were accidentally found during operation, but is not suited to cases that have symptoms and infection. He has not found that gallstones recur after treatment. Cholecystectomy, he thinks, will perhaps be the operation of the future, and it can be employed with almost equal safety with cholecystostomy.

16. **The Germicidal Action of Alcohol.**—The results of a series of experiments are reported by Harrington and Walker, who offer the following conclusions:

1. Against dry bacteria, absolute alcohol and ordinary commercial alcohol are wholly devoid of bactericidal power, even with twenty-four hours' direct contact, and other preparations of alcohol containing more than 70 per cent., by volume, are weak in this regard, according to their content of alcohol—the stronger in alcohol, the weaker in action.
2. Against the commoner, non-sporing, pathogenic bacteria in a moist condition, any strength of alcohol above 40 per cent., by volume, is effective within five minutes, and certain preparations within one minute.
3. Alcohol of less than 40 per cent. strength is too slow in action or too uncertain in results against pathogenic bacteria, whether moist or dry.
4. The most effective dilutions of alcohol against the strongly resistant (non-sporing) bacteria, such as the pus organisms, in the dry state, are those containing from 60 to 70 per cent., by volume, which strengths are equally efficient against the same organisms in a moist condition.
5. Unless the bacterial envelope contains a certain amount of moisture, it is impervious to strong alcohol; but dried bacteria, when brought into contact with dilute alcohol containing from 30 to 60 per cent. of water by volume, will absorb the necessary amount of water therefrom very quickly, and then the alcohol itself can reach the cell protoplasm and destroy it.
6. The stronger preparations of alcohol possess no advantage over 60 to 70 per cent. preparations, even when the bacteria are moist; therefore, and since they are inert against dry bacteria, they should not be employed at all as a means of securing an aseptic condition of the skin.
7. Provided the skin bacteria in the deeper parts can be brought into contact with *disinfectants*, alcohol of 60 to 70 per cent. strength may be depended on usually, but not always, to destroy them within five minutes.

19 *Congenital Dislocation of the Hip: Report of a Bloodless Reposition, Followed by Death, with an Analysis of Twenty-three Cases in Process of Treatment. (Concluded.) H. Augustus Wilson, J. Torrance Rugh and W. M. L. Coplin.
20 *Acute Leukemia. John B. Nichols.
21 *Retrocecal Appendicitis with Retroperitoneal Pelvic Abscess. A. Ernest Gallant.
22 Fracture of the Ischiopubic Ramus and Rupture of the Bladder; Recovery After Operation. Lindsay Peters.
23 Anomalies of Respiration in High Altitudes. W. A. Briggs.
24 A Rapid Method for Hardening and Embedding Tissues. B. Meade Bolton and D. L. Harris.

19. **Congenital Dislocation of the Hip.**—The article by Wilson, Rugh and Coplin gives the report of the one fatal case of bloodless operation for restoration of congenital hip-joint dislocation. The child was evidently of low vitality and the recent changes in the lungs and kidneys which were found were probably due to the anesthetic. The details of the postmortem are given in full.

20. **Acute Leukemia.**—This article, which is a portion of a paper awarded honorable mention in a prize competition in the District of Columbia, covers the subject of acute leukemia, reporting a case at length in which a peculiar coccus was found in the blood, but which did not appear to be capable of producing leukemia in animal inoculations.

21. **Retrocecal Appendicitis.**—Gallant reports three cases, the only ones in which he has found the abscess located in the pelvis behind the peritoneum. It has usually an acute onset and the abscess is usually readily recognized in its later stage by vaginal or rectal examination.

New York Medical Journal.

25 *In the Hemisphere of X-Ray Activity. J. Rudis-Jicinsky.
26 *The Ureteral Pelvis. Byron Robinson.
27 *Eclampsia—Its Prevention and Treatment. Edward A. Ayers.
28 *Atony of the Duodenum Diagnosticated and Corroborated by Operation. Mark I. Knapp.
29 *A Few Differential Diagnoses in Connection with the Exanthemata. William L. Somerset.

25. **The X-ray.**—One of the principal points made by Rudis-Jicinsky seems to be the greater effect of the *x*-rays in their sphere of greatest activity perpendicular to the anode. He illustrates it, showing the shading out of action, as the rays impinge less perpendicularly from the anode plate. He uses a protection of screen, shield, mask and lead box, with diaphragms for precluding the diffuse rays. This gives not only safe protection, but a very good opportunity to treat any lesion directly with the best radiation from the anode focus point, at the correct standard distance, through a speculum, or, if necessary, over the whole area with the lymphatic glands in surrounding infected tissues.

26. **The Ureteral Pelvis.**—Robinson's article is an elaborate anatomic description of the ureteral pelvis with its variations and relations to vessels, nerves, lymphatics, etc.

27. **Eclampsia.**—Ayers insists on the importance of prevention of eclampsia by proper diet and attention to the bowels. Keeping the bowels empty not only sustains the eliminative function, but permits the uterus to occupy the abdominal space with less interference with the work of the kidneys, ureter and heart. He also advises the patient to take a measure once a week of the entire urine passed in twenty-four hours, and having learned the normal amount, to inform the physician when any variation occurs. He holds that the increased abdominal pressure from the growing uterus has much to do with the development of eclampsia, and in all cases investigates this point. If the lower limbs or vulva are edematous or cyanosed he tries to keep the bowels empty and have the patient follow the rule of short periods of time on the feet and long periods of rest on the back and side. As regards the urine, he suggests the rule that whenever the amount excreted or the urea eliminated falls below the normal, or albuminuria or casts appear, treat the patient by diet, laxatives and diuretics to restore the functions to normal. If moderate effort does not succeed, exercise, diet, with active bowel and kidney stimulation, will sometimes cause death of the fetus, excite premature labor, or greatly weaken the mother. These strenuous results may not be called for. If there is headache, eye disturbances, furred tongue, cold, clammy skin and irritable pulse, we should not feel limited in the extent to

which we carry preventive measures. The indications for the induction of labor should be determined by a specialist. He suggests that it might be well to try the administration of thyroid extract when other methods fail. As regards the treatment of eclampsia, we must try to eliminate the toxins promptly and see whether we can do it without interfering with pregnancy. Many cases of eclampsia are the result of a very temporary condition of the emunctories. If, before the conditions have produced much cerebral hyperemia and asphyxiation of the blood, free catharsis can be secured, they may entirely cease and, by proper attention to warnings, a second attack be prevented. If the fetus has not been killed by the convulsions, the pregnancy may go to term. If it has killed the fetus, then labor can be induced in a gentle way after the toxic condition has been removed. Ayers condemns the plan of first attacking the convulsions and immediate emptying of the uterus. He thinks this gives the ideal results less chance to occur. We should not dull the nervous system with narcotics to lessen the response to elimination unless we add immediate delivery and perhaps blood letting. If the mind is clear and the effect of convulsions are marked he would give saline cathartics by the mouth and a high saline solution by the bowel. If the patient is highly nervous, with restlessness, tossing and mental activity, he favors the administration of 20 to 30 grains of chloral per rectum to relieve the nervous tension, not to produce narcosis. Nitroglycerin, 1/50 of a grain, should be given at the start and repeated as needed. If free catharsis is secured and the secretion of urine is not suppressed, and the convulsions lessen in an hour or two, he would not touch the uterus or further administer narcotics, but would use oxygen and hypodermoclysis with saline infusion. If following this treatment the attack ceases, eliminative treatment should be continued with lessening severity for one or two days, the diet being reduced to milk alone. The urine should be examined to see if the kidneys are acting normally. If not, labor should be induced by the bougie. The saline solution, he says, is one of the most valuable agents we have in obstetric work, particularly in hemorrhage, though in eclamptic cases its use requires more care. During convulsions the heart is laboring violently to empty its blood into the aorta and pulmonary artery, but is largely prevented by the respiratory spasm. By directly injecting into the vein at this time the strain is added to. He thinks as many cases in eclampsia die from exhaustion of the heart as from coma. For control of convulsions, when needed, he believes in the use of chloral by rectal injection, but its greatest danger is its effect on the heart. Veratrum viride is of value in cases showing a high tension. He would not be surprised to see it supplanted in the future by thyroid extract, which is a vasomotor depressant as well as a nervous stimulant, and this last action would seem perhaps to contraindicate it in eclampsia. However, he would not advise the use of any particular anticonvulsive as a routine measure, as no disease calls for more special selection than eclampsia. When labor is going to continue whether we check convulsions or not, it is best to hasten delivery. If the mental condition is active, the nervous system irritable, it is best to employ chloroform narcosis and dilate with judicious rapidity. He has had 46 cases of eclampsia with four deaths, and he thinks he has prevented a fatal termination in fully a score of cases. In all he has used nitroglycerin, chloral, chloroform and veratrum viride variously according to indications; dry and moist hot packs; saline infusion and injection; and various methods of cervical dilatation. In conclusion, he emphasizes two things: 1. That we can prevent the great majority of cases by careful application of the knowledge we possess; and 2, that in the treatment of cases each must be a law unto itself.

28. **Atony of the Duodenum.**—Knapp reports a case which he diagnosed as atony of the duodenum as against cancer, which was the other opinion given. There was a resistance at the left of the umbilicus running somewhat downward which he attributed to infiltration due to recurring attacks of pain in the abdomen, spasm and bowel distension. His reason for not diagnosing cancer was the intermittent character of the attacks, as in cancer, when the symptoms begin, they are continuous and not readily relieved by enemas, etc. The outcome of the case is given in the printed reports of the Presbyterian Hospital of New York for January, 1902. Operation revealed induration and thickening of the walls of the jejunum nearly obliterating its lumen, to which Knapp attributes the atony of the duodenum.

29. **Exanthemata.**—Somerset reports cases illustrating the difficulties of diagnosis and the differentiation of various exanthematous conditions. He remarks that the eruption of German measles is essentially macular, and only resembles that of scarlatina by confluence. Ordinarily the resemblance is rather to that of measles, but the crescentic arrangement is absent. It differs further from measles in giving a leucocytosis. With more profuse eruption, the resemblance is rather to scarlatina. Mild scarlatina and German measles may resemble each other very closely, but the strawberry tongue is never present in rötheln. The post-cervical glands are often enlarged, but by no means invariably so; conjunctivitis is exceptional; the temperature, pulse and clinical condition will not match the rash in scarlatinal proportion, and the eruption is apt to be patchy. German measles is more apt to be mistaken for scarlatina than scarlatina for German measles. He also reports a case of variola closely resembling varicella, and remarks that variola may abort and present itself in forms so divergent from the type that it deserves to be called varioloid or some other name, were it not that the contagion is as virulent in this case as in the most severe. The last case he reports is one of either quinin or ptomain poisoning resembling scarlatina.

30 *The Healing of Granulating Surfaces by Application of Cobalt-aurate Animal Membrane. Warren B. Outten.

30. **Cobalt-Aurate Animal Membrane.**—Outten recommends for granulating surfaces the application of fine gold-beater's skin soaked in a solution of cobalt chlorid, 1 ounce; gold chlorid, 1 dram, and distilled water, 10 ounces. Over this is poured 2 ounces of pure oil of cassia, which is also a germicide. He finds that the skin thus prepared is an excellent application to granulating surfaces. Before applying it the membrane is put in alcohol and allowed to stay there from three-quarters to one hour, and then in water from 98 to 100 F., to remove the excess of oil and alcohol. A few punctures are made through it after it is dried, and it is then applied to the granulating surfaces, and covered with sterile gauze. Another piece of membrane is applied on top of the gauze and over this a layer of sterilized cotton. No dressing which he has used on granulating surfaces is, according to Outten, equal to this.

40 A Graded and Systematized Plan of Outdoor Exercise for the Demented Insane. Chester L. Carlisle.
41 *The Final Chapter in the History of an Extensive Injury to the Head. H. P. Frost.

34. **The Blood in Mania and Melancholia.**—Fischer, who has investigated the blood in the so-called manic-depressive insanity of Kraepelin in the Connecticut Asylum, sums up her results in the following statements:

1. There are no pathognomonic blood changes in cases of maniacal phases of manic-depressive insanity. 2. Anemia is not a caus-

ative factor nor always an accompaniment of this psychosis. 3. The hemoglobin and red cells are frequently, if not always, increased during an attack of excitement. 4. A leucocytosis is an almost constant accompaniment and, I believe, a result of psychomotor activity. 5. That an increase in weight accompanies mental improvement.

36. **Psychiatry in Great Britain.**—Urquhart's contribution points out a number of advances in the practical side of psychiatry in Great Britain and notices also certain scientific studies, especially those of Mott in regard to the repair and decay of the nervous system and syphilis as a cause of insanity. There has also been good work done on phthisis and asylum dysentery, and nursing education has advanced. There has been better effort toward the organization of research and the same movement here manifest toward the treatment of incipient insanity in general hospitals has been in evidence in the British Isles. The legal treatment of insanity has been modified and the recognition of partial insanity demanding partial punishment is a notable fact. The works of Dr. Mercier, his psychology and his text-book on insanity are mentioned as the more important book contributions of the year.

37. **Puerperal Insanity.**—Jones recognizes a distinct form of insanity under this head, presenting marked delirium with wildness and hallucinatory delusions with religious and erotic features, which recognition, however, he admits is not in agreement with some high authorities. This is more particularly the insanity of parturition and the period immediately succeeding it. The insanities of lactation and pregnancy have no distinctive characteristics. In the type recognized, excitement is more common than depression, suicidal and infanticidal tendencies are frequent, heredity is marked in about 50 per cent., and while the disorder is usually considered among the curable types, it not seldom ends in terminal dementia. He considers the pathology of the condition, mentioning the possibilities of reflex processes of the crises of child-birth and also the absorption of toxins taken into the maternal circulation and irritating the nervous system. He favors asylum treatment for these cases, good nutrition, and the usual sanitary treatment of the puerperal condition.

39. **Tent-Life for the Insane.**—Wilsey reports an early experience in the Binghamton State Hospital in 1885, when patients were thus treated for certain periods with good results. The cause, however, was the crowding of the asylum rather than any therapeutic intent.

41. **Extensive Brain Injury.**—The case here reported by Frost was first reported by Rutherford in 1857. The man suffered a serious injury to the brain, destroying a large portion of the frontal and parietal bones, with apparent recovery. He was again reported in 1873, and was then in vigorous health, still again by Gray in 1876 and in 1888 by Bergtold under the title "Remote Effects in a Case of Extensive Injury of the Skull." At this time he was showing some physical and mental symptoms, unsteadiness of gait and some paresis of the facial muscles, atrophy in different parts of the trunk and limbs, and while free from delusions and hallucinations, was irritable and emotional. Thirteen years after this was written, in 1901, the patient was admitted to the Buffalo State Hospital for the Insane in a childish, irritable condition and somewhat demented, with paralysis, exaggerated reflexes, unequal pupils, etc. He died two years after entering the hospital, the cause of death being general debility due to his paralysis. The autopsy showed a large deficiency of bone on the right side extending from the external orbital process in front to the anterior margin of the occipital bone behind, and from the middle line above to within an inch of the external auditory meatus. The scalp and dura over this area were firmly adherent. The entire right hemisphere of the brain was markedly flattened and atrophied, the gyri presenting a shrunken or atrophied appearance with gaping sulci between. Microscopic examination showed a marked defect in the white matter with a much less advanced condition in the cortical gray. The theory is advanced that the direct pressure and loss of the protection of the cranial bones had the effect of interfering with the blood supply to the parts, and as the scar tissue contracted, the late symptoms of brain injury appeared. The article is fully illustrated.

12 *A Study of the Degenerations and Complications of Fibroid Tumors of the Uterus from the Standpoint of the Treatment of These Growths. Charles P. Noble.
13 Complete Nephro-ureterectomy. J. Wesley Bovée.
14 *Accidental Perforation of the Uterus. Abram Brothers.
15 *Gonorrheal Puerperal Fever. Fred J. Taussig.
16 Congenital Absence of the Uterus. W. A. Newman Dorland.

12. **Uterine Fibroids.**—Noble discusses the subject and points out the dangers of these growths, holding that one-third of the women having fibroids will die if not subjected to operation, while the mortality of myomectomy and hysterectomy is only 2 to 10 per cent. It is a fair conclusion that resort to early operation will affect a saving of 25 to 30 per cent. from the mortality in addition to a still greater saving in the morbidity.

14. **Accidental Perforation of the Uterus.**—Uterine perforation is a much more common accident, according to Brothers, than generally believed. The majority of cases never see the light of day because of the fear of criminal prosecution. It is rare, he thinks, for the condition to terminate fatally and the small mortality can be reduced to less than 1 per cent. if properly treated. He reports his own personal experience with it and reviews published cases. The proper course, he holds, is that when the uterus is perforated by the sound or curette to stop *any manipulation of the interior of the uterus*, especially uterine irrigations. If the curetting or sounding was preliminary to an intraperitoneal operation, this may be carried out, and the injury repaired with suture, but if no intraperitoneal operation was originally projected the patient can ordinarily be safely put to bed with an ice-bag over the hypogastrium and given morphin or opiates. If the uterus has been injured and the operator has irrigated the uterine interior, there may be a mild local peritonitis, requiring the same method of treatment as above, or a septic peritonitis may call for immediate hysterectomy with drainage through the vagina, or lastly, there may be a localized abscess in the pelvic connective tissue or pelvic peritoneum which may require to be attacked from above or below. Operation in most of these cases will be of the nature of an exploratory laparotomy, and the exact line of work be determined on when the abdominal cavity is opened. When the uterus has been injured and the intestine has been dragged through the wound and strangulated, laparotomy must be done as early as possible, resection of the intestine be performed if necessary, and the uterus repaired or removed as indicated. Even this condition is not necessarily fatal. Miquel has reported five recoveries in eight operations.

15. **Gonorrheal Puerperal Fever.**—The essential points regarding gonorrheal puerperal fever are stated by Taussig as follows: The gonococcus is the etiologic factor in about one-sixth of all cases of puerperal infection, and though almost invariably secondary to the gonorrheal process elsewhere, must be classified under the head of puerperal fever. The gonococcus may gain access to the uterine cavity without any internal examination being made, but more frequently it is brought about by digital examination and operative manipulations, particularly intrauterine, in delivery, etc. The infection shows itself at the sixth or eighth day postpartum by rigors, a temperature of 103 and severe abdominal pains. The fever is usually of short duration and the further course of the disease is mild, but liable to become chronic. Where the temperature begins to rise as early as the sixth day and continues to rise up to 103 or 104, it is still not necessarily caused by mixed infection, but may be due to the gonococcus alone. The diagnosis is based on the rather late onset, the slow, regular pulse, the moderate and steady elevation of temperature, the profuse purulent, glairy discharge, and, above all, the presence of gonococci in the lochia. Prophylaxis is of more benefit than treatment. All pregnant women having gonorrhea should be delivered without internal examination as far as possible. The treatment should be limited to one or two uterine douches, frequent vaginal irrigations and prolonged rest in bed.

55 The Uterine Incision in Cesarean Section. Churchill Carmalt.
56 The Surgical Treatment of Uterine Fibroma. Brooks H. Wells.

48. **Puerperal Infection.**—The treatment here advocated by Wetherill consists in rest in bed, no purges, no food by the mouth, lavage if nausea and vomiting occur, rectal feeding with stimulating and predigested foods in small amounts every four to six hours, and salt solution by the rectum, hypodermoclysis or intravenous injection as required. Once a day a cleansing rectal enema. Strychnia or other stimulants hypodermically. For local treatment he believes in the alcohol method of Carossa, using a special double-current drainage tube, which he illustrates, packing the vagina with gauze and having the nurse instructed to inject into the tube at short intervals from two to four ounces of 50 per cent. alcohol, thus flushing and cleansing the uterine cavity and retarding septic diffusion throughout the lymphatics. He leaves the tube and gauze *in situ* for from three days to two weeks, keeping them free from obstruction by a good piston syringe. The results of this treatment, he claims, are excellent. Regarding surgical measures in puerperal sepsis, he adds that his experience with the various methods teaches him to never operate during the acute stage except as a last resort, and then always with the worst possible prognosis.

53. **Pruritus Vulvae.**—Balloch describes the condition and reports a case which terminated in kraurosis, and was operated on by resection. He believes that the success of excision in kraurosis makes it advisable in simple pruritus after a reasonable trial of the ordinary remedies.

54. **Lactation.**—Drennan holds that normal lactation could be kept up for much longer periods than is customary at the present time if only men and women lived in a natural manner and avoided sexual excitement during the function.

57. **Peritonsillar Abscess.**—The title of this paper, the author says, should perhaps have been "the location of pus in peritonsillar abscess," as that is the point to which he directs special attention. He finds three locations claimed as possible situations: 1. The pharyngomaxillary fossa; 2, the supratonsillar fossa; 3, the loose connective tissue underneath the mucous membrane surrounding tonsil or fossa. From his discussion of the anatomic conditions he concludes that the real site of the abscess is in the areolar tissue. The practical points of incision are given by him as follows: An upward and backward one, using a straight knife for anterior-superior cases; while for postero-superior an outward incision between posterior pillar and tonsil, with a right-angled knife, is advised.

60. **Laryngeal Paralysis in Tabes.**—Lockard concludes that laryngeal paralysis is present as a complication in about 15 per cent. of all cases of tabes and may precede all other symptoms from six months to three years. It is always limited to the posticus muscle and is usually, if not always, unilateral. It usually remains limited to this muscle for years or during life. This primary paralysis is fairly common, but owing to the lack of subjective symptoms the true percentage can not be ascertained. When the cause of abductor paralysis can not be correctly ascertained tabes should be thought of. It is frequently of great diagnostic importance, drawing attention to the general condition and sometimes reveals an unsuspected ataxia. Wherever the diagnosis of tabes is doubtful, a laryngeal examination should be made, whether or not there be subjective laryngeal symptoms. He reports cases.

61. **Recurrent Mastoiditis.**—Within the last few months Dench has operated on nine cases in which a previous mastoid operation had been performed and persistent sinusitis or recurrent inflammation occurred. In every case the exposure revealed dead bone in the tympanic vault and other anomalies in the walls. It is his practice in these cases to perform the ordinary Stacke-Schwartze operation, and he believes that we should not be content with relieving the immediate acute symptoms by doing a simple mastoid operation in acute mastoiditis. Wherever he finds that the patient has had an aural discharge previous to an acute attack he immediately does the radical operation.

62. **Septal Abscess.**—Coakley employs the Simpson tampon in cases of septal abscess to keep the two layers of the muco-perichondrium in close juxtaposition during healing and at the same time to help bear the weight of the superimposed soft parts until the newly-formed connective tissue is of sufficient density to support them unaided. At the end of a week some form of hollow nasal splint may be substituted for the Simpson tampons to prevent the continuation of mouth breathing.

63. **Auditory Vertigo.**—Crockett advises in the severe form of auditory vertigo, after ordinary treatment has proved futile, the removal of the stapes, and reports cases. His technic is as follows: A flap is made of practically the whole posterior quadrant of the membrane, putting the knife in behind the umbo and carrying it upward close to the posterior edge of the malleus, then across posteriorly and down the posterior superior wall. This flap is then turned downward. The incudostapedial articulation is then cut, if possible, from behind forward. The long process of the incus is then seized with a Sexton forceps and the ossicle removed by traction. The stapedius tendon is then cut and a blunt-pointed hook passed between the crura and the stapes and the stapes removed by traction a little upward and outward. The operation is very painful and generally an anesthetic is advisable. In both cases which he reports total deafness resulted. There was also an increase of tinnitus, which he attributes to hemorrhage in the internal ear, but the ultimate results were good. He advises also *always to explain the fact that total deafness* may be the result of the operation, though the tinnitus may be ultimately relieved.

64. **Prognosis in Chronic Suppurative Otitis.**—From his study of the subject, Harris offers the following deductions:

1. Chronic otorrhea in a large percentage of cases is amenable to suitable medical treatment. 2. In addition to proper attention of a general character and to the naso-pharynx, peroxid of hydrogen, with or without formalin solution, gives the best results, all minor operative procedures of course first being attended to when necessary. 3. The results of such treatment are in a good number of cases permanent. 4. The risk of an uncured otorrhea with good drainage is relatively very small (1/2 or 2/3 of fatalities). 5. Medical treatment failing, after a suitable interval of time, the danger of fatal complications in absence of all symptoms should be laid before the patient and the promise of relief by operation

stated. 6. Where there is no good reason to the contrary, such as intracranial or mastoid complications, the intratympanic method by ossiculectomy should be preferred, (*a*) because its results as regards the cure are equally good; (*b*) the risk of loss of hearing is vastly less; (*c*) the danger of unpleasant sequelæ, such as facial palsy, is avoided, and (*d*) the possibility of prolonged after-treatment is obviated. 7. The radical operation is not without risk of life. 8. Where ossiculectomy fails or mastoid or other symptoms exist pointing to extension of the disease into the bone, the radical operation then becomes the suitable and valuable method of relief. 9. The protecting and assisting power of nature is never to be lost sight of.

80 A Test for Central Color-Perception. Percy Fridenberg.

71. **Cicatricial Ectropium.**—Hotz reports a method of preventing the after-contraction of the lids in the operation for cicatricial ectropium. He avoids traction of the shortened flap on the lid border by dividing the wound area into two sections, one representing the surface of the lid and the other section the wound surface beyond the lid, covering each section with a separate skin flap, anchoring the flap and covering the lid surface so securely that the contraction of the other flap can have no effect on it. In the case of cicatricial ectropium of the upper lid he anchors the lid flap to the tarsus, and in the lower lid to the tarso-orbital fascia. The technic is described in detail.

83 *The Physiologic Basis of Manual Therapy and the Rôle of the Vasomotor Mechanism. John P. Arnold.
84 Adrenalin Chlorid in Pulmonary Hemorrhage and Epistaxis. Edward A. Robinson.

81. **Membranous Croup and Diphtheria.**—From a careful consideration of the subject Ellegood concludes that there is no such disease as true membranous croup; that pseudo-membranous inflammation of the mucous membrane of croupous or diphtheritic type, whether or not followed by paralysis, is always caused by the Klebs-Loeffler bacillus in some phase of its existence. This bacillus is a facultative saprophyte. The virulent and the non-virulent types are of the same genus of micro-organisms, and the non-virulent type is the same organism undergoing a kind of saprophytic state of existence which is interpolated in the life history of the parasitic bacillus. The degree of toxicity manifested depends on certain unknown vital conditions of the micro-organism, and on the anatomic character of the part attacked, the degree of immunity possessed and the effect on the germs and its toxins of associated bacilli. Isolated cases of diphtheria, or those which do not give rise to infection, are as frequent as the cases of membranous inflammation of the larynx in which the membrane is confined to that organ without giving rise to infection or to the constitutional symptoms of diphtheria. The failure to find the specific bacillus in a small proportion of cases is due to faulty technic, the late stage in the disease at which the bacteriologic examination was made, unknown morphologic conditions of the micro-organisms, to the development of peculiar or unusual relations to staining reagents, to autolysis, or to the action of other bacteria. Antitoxin when administered early in uncomplicated cases is an almost unfailing remedy, and is useful in all cases. He holds that the occurrence of the bacillus in healthy persons should be carefully investigated, as they are as dangerous as diseased ones.

82. **Exophthalmic Goiter.**—The pathology of Graves' disease offered by Blake is that it is a sort of petrified terror. He thinks there are a number of agencies that can produce this condition, such as staphylotoxin, streptotoxin, intestinal poisons, malarial plasmodium, septic products and probably vitiated respired air, and possibly other causes. He considers the success of iodids and fluorids in this disease as due to their antitoxic and germicidal products. The real aim of treatment should be to attack its cause. He has witnessed cases of the disease which recovered rapidly after removal of colonies of staphylococci and streptococci from the buccal and pelvic cavities.

83. **Manual Therapy.**—The basis of manual therapy, according to Arnold, can be looked for in the vasomotor mechanism. This should be thoroughly understood by the physician.

89 *The Methods of Administration of Anesthetics. Edward Martin.
90 *Potassium Iodid in Migraine. J. R. Clemens.
91 On the Therapeutic Value of the Nuclein Compounds. James Burnet.

85. **Alcohol.**—This experimental investigation by Hare leads to the conclusion that alcohol seems to have the power of increasing the bacteria-destroying action of the blood in infectious diseases, and while the experiments thus made are too few to determine the question and are also somewhat contradictory, they indicate, so far as they go, that this effect is produced, to some extent at least, by an increase in complement.

87. **Anesthesia.**—The preparation of the patient for the anesthetic is the subject of Clark's paper, which points out the pulmonary conditions contraindicating anesthesia, among the first of which he includes bad colds. The patient suffering from coryza runs the risk of pneumonia, and this is a serious contraindication to anesthesia. A cold is almost invariably made worse by an anesthetic. In chronic bronchitis, however, the anesthetic may even improve matters. The stimulation of the ethereal irritating vapor apparently assists in overcoming the chronic bronchial inflammation. Pulmonary tuberculosis, if localized with sufficient lung space still for respiration, is *not*, as a rule, rendered worse. Chronic emphysema is always a serious contraindication. In heart troubles the danger is not from profound anesthesia, but rather from the early stages of its administration. The stage of excitement should be avoided as much as possible by giving ether or chloroform very slowly, so that the passage between consciousness and deep anesthesia is very gradual. As a rule, therefore, cardiac lesions are *not contraindications*, unless there is a serious failure in compensation. Next in importance he insists on careful examination of the urine. Renal insufficiency with a small trace of albumin is much more significant of danger than a considerable amount of albumin with an approximately normal quantity of urine. He has found that ether rarely produces serious kidney lesions if the anesthesia has been in skilled hands. The chief indication, admitting the contraindications mentioned, is to directly evacuate the alimentary tract and to cleanse the blood of the by-products that are to be excreted by the kidneys, so that in the one or two days following the operation the patient's excretory apparatus may undertake unhindered the elimination of the nitrogenous and waste products arising from the ether intoxication and from the increased metabolism incident to any operation or infection. He advises the use of an increased amount of fluids up to two hours before the operation, so as to increase the watery constituents of the blood and dilute the irritant products, and gives calomel in .5 gr. doses every half hour until two grains are taken, followed by an enema three hours before the operation. Bromids, morphin, etc., to prevent nausea have not been satisfactory. The other minor details, such as the removal of false teeth, the abstinence from food for six hours, are well known.

88. **The Choice of an Anesthetic.**—Davis holds that ether is generally to be used unless it is contraindicated, but he has seen fatal results, and emphasizes that it also requires the exercise of care and precaution in its use. He would prefer Willy Meyer's anesthol to chloroform, but ether is less depressing and, therefore, is to be used in preference to either

wherever shock is liable to be a prominent factor. In very old persons the tendency to bronchitis makes chloroform the more desirable, and also in lung troubles and in alcoholics. In certain operations on the brain, mouth or throat, chloroform or anesthol is to be preferred. In genitourinary work he would prefer ether. The preceding administration of nitrous oxid has much to recommend it as rendering anesthesia easier and more satisfactory. Nitrous oxid gas is familiar to every one. Bromid of ethyl is hardly a safe anesthetic, and he does not recommend it. Kelene or ethyl chlorid is considered by Ware of New York as about midway in safety between nitrous oxid and ether. In conclusion he calls attention to the primary anesthesia which can be obtained with ether, and which will be found in many cases for short operations perfectly satisfactory, and yet not have the uncomfortable after-effects of full anesthesia.

89. **Anesthesia.**—Martin would use nitrous oxid for brief operations, ethyl chlorid for fast work to some extent, though its safety is still a matter of question. Ether is the best and safest anesthetic for major surgical procedures. Chloroform can be used in brain surgery and in patients suffering from inflammatory lesions of the air passages. It has been clearly shown that its irritating effect on the kidneys has been greater than that of ether.

90. **Potassium Iodid in Migraine.**—Clemens has been lately prescribing potassium iodid to the exclusion of all other drugs in migraine headache, and the results have been so remarkable that he offers his experience to the profession. The reasons which induced him to give it were the similarity between migraine and cerebral syphilis and the raised arterial tension. He gives 5 to 10 grains of potassium iodid three times daily and finds that after two or three weeks the headache is completely eradicated. He has not met a case that was not absolutely cured. He notes as a significant point in treatment that the headache can be recalled by simply discontinuing the drug for a few days.

1. **Antiarin.**—Seligman has investigated the action and active principle of the Kenyah dart poisoning of Borneo and its active principle, antiarin, and finds that it acts on the ventricle of the heart as a poison of the digitalis group. This has been noted by all previous observers. It also causes paralysis of the central nervous system and temporary chronic spasm of the

voluntary muscles. In mammals or birds the gastro-intestinal symptoms are usually added to the above effects, though certain birds, however, are comparatively immune. His preparation of antiarin, a crystalline glucoside, lacked the convulsive effect of the crude substance, Kiliani's antiarin investigated by Hedbom, though as a cardiac toxin it was fully as active.

2. **Drug Eruptions.**—The drug eruptions noted by Pernet are erythematous, urticarial, papular and desquamating rashes produced by belladonna, arsenic, iodoform, copaiba, quinin and salicin, digitalis, etc. Borax has been said to cause psoriasis. He questions this statement, but admits that it is possible. Chloral hydrate deserves special notice. The eruptions produced are usually erythematous in type. He also mentions the erythema following chloroform and ether and the antitoxin rashes. The diagnosis is noted at length. Erythema multiforme, he remarks, has been closely imitated by drug rashes. In the arsenic beer poisoning epidemic in England recently, many of the cases closely resembled this type. When psoriasis, lichen planus or syphilides are simulated the duration of the corroborative symptoms should be taken into account. Headache, for example, would suggest antipyrin. If copaiba is suspected, a gonorrheal discharge will be of assistance. In localized dermatitis he suggests our looking out for the pediculus pubis and the application of mercurial ointment. The vesicular and bullous lesions are at times mixed up with erythematous and papular ones, indicating severer action of the drug. Salipyrin has produced something in this line. The author remarks that bullous eruptions are greatly aggravated by potassium iodid given internally. Arsenic may give rise to zoster. The iodid of potassium eruptions are more commonly pustular, but vesicles and bullæ are sometimes seen. Of the pustular eruptions those of bromid and iodid origin are the more notable, but arsenic, salicylic acid, etc., have occasionally produced them. The distinctive characteristics of the bromid and iodid rashes are noted. Furuncular complications sometimes occur from the use of these drugs, and gangrene has been produced by arsenic, quinin and also after orthoform locally applied. (The author does not mention the carbolic acid gangrene in this connection.) Pigmentation is a matter of interest and importance and has lately been prominently brought before the medical profession by the Manchester arsenical epidemic. The argyria produced by the nitrate of silver formerly used for epilepsy is a notable instance of this type. Keratosis or hyperkeratosis is seen in arsenical poisoning. Tumor-like lesions may occur in bromic or iodid eruptions. The condition of the nails and hair should be noted in connection with arsenical and quinin intoxication. He suggests as regards etiology that the gastrointestinal condition may be of importance. The nervous system can not be neglected, though its influence has been overrated. There is a great difference in individuals, though raising the question of idiosyncrasy, he says, "burkes the question of causation." *In the treatment the first thing to do is to stop the offending remedy.* A certain amount of diarrhea in these cases should not be interfered with. It is important not to push drugs which, instead of ameliorating morbid skin conditions, do exactly the contrary. In bromid eruptions arsenic is of assistance. The prognosis is favorable as a rule, though hopeless in the nitrate of silver cases. These, however, are rare nowadays.

4. **Experimental Hemoglobinuria.**—Manson reports the case of a young man who believed that the administration of quinin produced blackwater fever, and was perfectly willing to have the effect demonstrated. The observation was made and a mild case of blackwater fever produced. The case is one more proof that in some individuals, under certain unknown conditions, quinin produces hemoglobinuria.

11. **Paraffin Prothesis.**—Paget first reviews the history of this method, giving full credit to Gersuny as its originator, and describes the technic, preferring the heating point for paraffin between 108 and 115 degrees F. in ordinary cases, but where it has to stand heavy and immediate pressure the higher heating point is desirable. All paraffin shrinks, but this is slight and may be practically ignored. He has done 43 cases of nose remodeling without accident, with no death, no embolism, no sloughing of the skin and no wandering of paraffin into the eyelids. The results were permanent in some cases, improvement in some is only partial, others fairly good, and in still others but slight. Some cases that seem hopeless do very well, and others that look easy are found difficult. While the chief causes of shrunken noses are injury, inherited and acquired syphilis, there is a set of cases where it is due to abscess in the nose in childhood and others where there is no history at all. The skin in these cases *must* be loose and not cicatricial. That is the most important thing in results. If it is fairly loose, soft and healthy, and it can be picked up between the finger and thumb, one can be sure of doing good, but there is danger of failure and disappointment if it is tight and hidebound or cicatrized and fastened by adhesions. He mentions in conclusion the use of paraffin for the holding up of the prolapsed bowel or uterus. He would not advise it in uterine cases if the pessary will make the patient comfortable, for there is a slight risk of embolism. The general procedure is much the same in both, only that in the uterus the prolapse may need a large quantity of paraffin and care should be taken to avoid the bladder or rectum. The bulk of the paraffin should be put under the mucous membrane of the posterior vaginal wall and at the sides of the vagina. In the cases he operated on for this purpose his success astonished him. It should not be used, however, in cases during the child-bearing period, as it prevents this function.

14. **Brain Injury.**—Harman and Bradburne report the case of a man shot through the head in the Boer war, giving diagrams showing the exact course of the bullet, which passed from the anterior portion of the parietal down to near the external occipital protuberance, the wound being clean both in entrance and exit. The patient had a transient motor paresis and hemianopsia. The former was nearly recovered from while the latter seemed to be permanent. One point of importance is specially mentioned, the rim of blindness found along the left side of the left field, indicating the existence of a defect in the area held to be supplied by nerve fibers connected with the right uninjured hemisphere. This can be accounted for either according to the Charcot hypothesis of a double decussation of the optic nerve and its connections, one at the chiasma and another in the hemisphere, or the supposition of an injury also to the right hemisphere. The latter is the theory that is favored. The general conclusion from the case is that the central area of the visual field has its cortical connection toward the apex of the cuneus, and supports the view that the perceptive center for vision is situated in the occipital and cuneate regions rather than in the more anterior angular gyrus. The case gives no information as regards the psychic visual center.

19. **Pilocarpin in Pneumonia.**—Several cases are reported in which pilocarpin injected in doses of 1/10 of a grain hypodermically caused almost immediate arrest of the unpleasant symptoms of pneumonia, also diminished pleuritic pain, etc. From his limited experience Curtin concludes that pilocarpin will have a leading place in the treatment of pneumonia, relieving the pain and breathing and sometimes also hastening resolution by exciting glandular secretion. Its administration in most cases is followed by an immediate rise of temperature of ½ to 1½ degrees. One-tenth of a grain dose hypoderm-

ically does not cause profuse perspiration, and but rarely fails to reduce the temperature within an hour or two. It also cleans the tongue and stimulates the flow of saliva. He has not noticed its repeated administration attended by any undesirable results. As a precaution he emphasizes the importance of keeping the patient warm, especially the feet.

27. See Paragraph 4 above. The authors here suggest that the antecedents of the case seem to indicate that the hemoglobinuric idiosyncrasy may have been due to neglect of the use of quinin in the earlier stages of what may be a special form of malarial infection, and consequent development of an intense and peculiar cachexia.

57 Measurements of Fetal Head. Vallois.—Note sur les diamètres de la tête fetale à terme.

50. **Fate of Prematurely-Born Infants.**—Maygrier has found that 45 out of 48 infants born soon after the sixth month and weighing less than 2.500 gm., followed to date are alive and well. The mortality was 19.4 per cent. out of 597 such births at Lariboisière Hospital and 10.12 per cent. in 316 at the Charité.

51. **Lactation During Disease.**—Budin describes 19 cases of grippe, uterine, puerperal or other infection occurring in women nursing new-born infants. The breasts were washed with a weak solution of sublimate and then with boiled water before the child was nursed, and he was kept entirely away from the mother during the intervals between nursing. No unfavorable results were noted in any instance.

64 *Enterectomie aseptique. Enterorrhaphie circulaire rapide par la suture; instrumentation et technique opératoire. E. Vidal (Périgueux).

58. **Diagnostic Value of Leucocyte Count.**—The findings were so constant in 25 cases of gynecologic affections in which the blood count was carefully studied that Bérard and Descos affirm with great positiveness that it is possible to determine by the leucocyte count whether or not there is suppuration and whether the germs are virulent or not. In affections in the female genital sphere when the leucocytes number 12,000 to 13,000 or more, with decided increase in the polynuclear cells—80 to 85 per hundred—some suppurative lesion exists or is forming, as, for instance, an infected hematocele. The pus is virulent. Intervention should be postponed if possible. If operation is necessary it should be by the vaginal route, and strenuous efforts made to prevent sowing the germs on the peritoneum. When the leucocytes number 10,000 or under, either there is no pus or it is scarcely at all virulent, and operation can be undertaken with the peritoneum walled off from the field with tampons and sponges. In case of profound infection, the leucocytosis indicates the moment for surgical intervention. While awaiting it the general condition should be improved, by injections of serum, fixation abscesses, etc., until the acute phase is past and the leucocyte count shows that the virulence is becoming attenuated. This is especially necessary in case of streptococcus infection. If the leucocyte count drops from 25,000 to 12,000 or thereabouts, the germs have lost their virulence or else the reaction on the part of the organism is so decided that the surgeon can operate without fear. Of course when there are other clinical symptoms of severe infection and the leucocyte count remains constantly low, the prognosis is grave as this signifies that the cellular defenses are unable to cope with the virulence of the infection.

59. **Vaginal Mechanical Dysmenorrhea.**—Menstruation proceeded normally for two years in the case described, but after an attack of scarlet fever it was always painful. Examination disclosed a stricture in the vagina just below the cervix, nearly obliterating its lumen.

60 and 61. **Segregation of Urine in Bladder.**—Luys' instrument has been used in 85 cases and Cathelin's in 83. Both give satisfactory results according to the writers, and are described in detail with 10 and 11 cuts and a colored plate.

62. **Condition of Adnexa in Case of Uterine Fibromata.**—Daniel concludes from anatomic study of 205 cases and analysis of 136 published, that the tubo-ovarian apparatus is pathologic in fully 59 per cent. of all cases of uterine fibromata, if not macroscopically, at least microscopically and histologically. There are evidences of inflammation in about half this number,

but in the others the influence of the fibroma is manifested in circulatory disturbances secondary to the action of the pelvic varicocele or to mechanical irritation of the peritoneum by the tumor or in the general influence of the neoplastic diathesis. Neoplastic affections in the uterus are, therefore, reflected in the adnexa as well as the inflammatory. In some cases the symptoms from the annexes are the first to suggest the tumor formation.

64. **Aseptic Enterectomy and Suture.**—Vidal thinks that he has solved the problem of opening the intestine late in the operation, with solid union of the two serous surfaces during the suture, and a firm support for the suture which does not have to be left in the intestine. After clamping and ligating, he resects the intestine and brings the two ligated stumps together. He inserts in each stump, close to the end, an instrument he has devised which folds together flat until it looks something like an ordinary buttonhook. The curved end is worked through a small buttonhole in the intestine close to the ligated stump. The instrument is then opened and the two half circles form a solid ring, which is pressed against the ligated end, stretching the lumen. A second, similar instrument is introduced into the other stump to correspond. The two stumps are thus stretched as if on hoops, and by pressing these two hoops together, the stumps are approximated and can be conveniently sutured. The ligature is tied in a special knot, which is untied by pulling on the end projecting through the buttonhole. Each hoop is then folded again into the flat semicircle and removed through the buttonhole, which is sutured. The loose end of the previously ligated stump spreads out into a narrow curtain inside the intestine after the ligature is removed. These curtains slough off but serve at first to protect the suture. The article is profusely illustrated.

67. **Alcohol as Protection in Disease.**—Clemm reviews a number of established facts showing the efficacy of large doses of alcohol in preventing injury from snake bites, etc., and the strange absence of alcoholic intoxication in these circumstances. He quotes Nothnagel's advice to treat incipient grippe with brandy. Runge has also advised large amounts of alcoholic drinks in puerperal fever. Brehmer advocated alcohol in febrile tuberculosis and Mircoli has recently argued in favor of its "sero-antitoxicity," and commended it as a valuable adjuvant in treatment of tuberculosis as mentioned in these columns. The efficacy of alcohol in these varied conditions may be explained by several hypotheses. It may precipitate the toxic substances in the blood and render them harmless, or it may influence the nerve centers until they cease to feel the influence of the toxins, or the molecular structure of the latter may be altered and the toxicity thus diminished. There is also a possibility that the osmotic tension may be altered by the alcohol and greater bactericidal power conferred on the more concentrated blood. In febrile affections, therefore, the value of alcohol is not so much to whip up the heart as to keep toxins away from the heart. The use of large doses of alcohol is apparently justified in diseases in which the pathogenic germs generate a toxic albuminoid. Study of the composition of the bacterial toxins generated in various diseases may suggest other valuable hints for treatment.

85 Die Prophylaxie in der Psychiatrie. A. Cramer (Gottingen).

80. **Transient Aphasia.**—Rothmann describes 3 cases of acute transient aphasia which emphasize the varieties of causes that may induce it. In one case the total aphasia appeared with an apoplectic attack. The subject had been exposed to the summer sun at noon, but as the disturbances did not occur until several hours later they were probably due to toxic substances evolved in the interim. There was total unconsciousness at first, the right hemisphere then rapidly recuperated and all symptoms vanished except the aphasia, which lasted for an hour. The second patient was a young physician who has since become a noted pioneer in the study of the brain. The factors in his case were overstudy, exposure to the sun, a fall from a horse and an unusually hearty meal. Pure motor aphasia was followed by agraphia and paraphasia, with complete recovery in less than an hour. In the third case total motor aphasia with right hemiplegia developed suddenly during convalescence from pneumonia and vanished completely in less than half an hour. The next day the aphasia returned with almost total right hemiplegia, both persisting for months. The capacity to sing was retained and nearly normal speech was regained in time by means of exercises conducted in singing tones. The heart was apparently intact in this case and the trouble was evidently due to embolism in the left hemisphere. The thrombosis probably originated in the pulmonary veins. This experience suggests caution in assuming that transient aphasia is of merely functional nature. It may be the result of toxic action from substances generated by external influences, emotions, traumatisms, overexertion, etc., as well as from embolism.

83. **Puerperal Struma.**—Malade has witnessed three cases in which the thyroid gland swelled in multiparæ during parturition. In one instance it was the direct or indirect cause of fatal anemia of the brain.

84. **Polymyositis.**—Oppenheim's five cases of polymyositis demonstrate that the mucosæ are affected as an essential feature of the affection. The mucosæ of cheek, tongue, palate, and conjunctiva are liable to be involved. The redness, swelling, pain, difficulty in swallowing and hoarseness were supplemented in some of the cases by multiple small ulcerations on the mucosæ. In one instance submucous hemorrhages left an Addisonian pigmentation. In another there was double iritis as well as conjunctivitis. He urges study of this form by ophthalmologists who may encounter abortive forms. Oppenheim proposes the name dermatomucomyositis for this affection and calls attention to a possible connection with syringomyelia. In one case the affection in a boy of 8 gradually assumed more the aspect of syringomyelia, and now, four years later, the clinical picture resembles more the latter. Others have reported very discouraging results from treatment, but energetic diaphoresis has accomplished wonders in his hands. He first applies hot air and then wraps in blankets, giving hot drinks and aspirin. The patient is thus sweated for an hour every second day at least, alternating with thermomassage and later simple massage, gymnastics and electricity. Improvement was soon marked under this régime, and complete recovery followed, although the last traces of the affection did not vanish in 2 cases until after a winter in the south.

86. Seasickness Due to Anemia of the Brain.—Binz learned that a person taking a certain patent medicine vaunted as a preventive of seasickness, slept while under its influence and did not lose her ruddy coloring, and escaped her usual attack of seasickness. He analyzed the medicine and found it merely a mixture of chloral hydrate, of which 1 gm. was taken in three doses. The absence of pallor induced him to experiment on rabbits and he found that the blood in the ears and surface of the brain ebbs and flows synchronously. These and other facts which he details suggested to him that the cause of seasickness is merely anemia of the brain, to which the pallor testifies. It is a familiar fact that anemia of the brain induces nausea and vomiting; while chloral dilates the cerebral vessels and thus prevents anemia and hence might protect against seasickness. He does not attempt to explain why the rocking of the ship induces anemia of the brain, but is convinced that it does so. The retching and vomiting induced by this anemia in the brain call the abdominal muscles into play, and this in turn drives the blood back to the head and the symptoms are arrested for the time being. The stomach has only a passive rôle in seasickness and is incited to vomiting by the brain, regardless of whether it is full or empty. Everything that tends to promote and increase the flow of blood to the brain has a prophylactic, relieving or curative action in this affection. The brain should be nourished with strengthening food and the blood supply favored by the horizontal position and medicinally by drugs that dilate the blood vessels in the brain. Chloral hydrate, potassium bromid, amyl nitrite and antipyrin might be tentatively tried.

88. Cryoscopy in Liver Affections.—Ferrannini states that the freezing-point in 4 cases of atrophic venous cirrhosis ranged from —.55 to —.75 C.

93. Urea in Transudates and Exudates.—Ulrici found an average of .485 per cent. of urea in pericarditic effusions and .019 per cent. in pleuritic effusions.

94. Transient Amaurosis in Uremia, Eclampsia and Lead Poisoning.—The transient amaurosis sometimes observed in these different affections is due to the vascular tension common to all three. It vanishes as the tension becomes relaxed.

96. Genesis of Pulmonary Tuberculosis.—Aufrecht is convinced that the germs enter the system by way of the tonsils. The passage of the bacilli into the blood is explained by the permeability of the intact vessel wall for tubercle bacilli from swollen and adherent lymph glands. This permeability is now established beyond question, and solves the problem of the migration of the germs from tuberculous glands in neck and mediastinum. He regards scrofula as the main factor in the predisposition to tuberculosis, and defines the essence of scrofula as a congenital or acquired enhanced permeability of the vessel walls for the elements of the blood and the bacteria circulating in it. The apex offers the most favorable point for the settling of bacilli that have found their way into the pulmonary arteries or veins on account of its defective circulation and also the stress of mechanical action. Sedentary occupations render the circulation in the apices still more defective than naturally. The apex also suffers from traction of muscles during exercise. Violent coughing causes a backward stagnation of air in the apices as they are covered only by soft parts, which do not participate in expelling the air. These factors may have injured the apex before the arrival of the bacteria. As they proliferate in some small blood vessel in the apex they make the walls thicker by their own bulk and disturb the blood supply in the parts irrigated by the vessel. The result is a little patch of necrosis in which the bacilli settle and the caseous tubercle is the result. It is the product of the combined action of the necrosis and of the bacilli. The area involved may heal after the necrotic caseous patch has been thrown off or transformed into a fibrous nodule. Healing is hindered by the irritation of the lung tissue from the presence of the caseous patch as a foreign element in the confined space. This irritation induces infiltration, and as this develops and spreads, pulmonary phthisis is established. The cavity is due to the breaking down of the infiltrated tissue, and treatment should aim to prevent or arrest these secondary pneumonic processes, with specific treatment to exterminate the primary bacterial agents.

98. Heat Production.—The results of the comprehensive research conducted by Hirsch, Müller and Rolly, at Leipsic, demonstrate that the glands, and especially the liver, have a larger share in the production of heat than has hitherto been credited to them. Among the phenomena that favor this view is the rapid disappearance of glycogen in the liver and the suspension of glycosuria during fever in a diabetic. There are evidently two parallel processes in the production of heat, 1, a specific destruction of albumin modified by the action of toxins, and 2, a central irritation or stimulation in the sense of the hyperthermia induced by puncture of a heat center.

104. Duration of Life and Working Capacity in Pulmonary Tuberculosis.—Stadler has collected statistics which show that tuberculous subjects live on an average at least six to seven years after infection. The course of the disease does not seem to be modified by injurious professional conditions, and hence a change of occupation is not imperative. Some degree of working capacity continues on an average until after the fifth year in about half of those affected. In his experience at the Marburg polyclinic, out of each 100 of the patients engaged in indoor work 23 were tuberculous; 22 in each 100 with out-of-door occupations, and 29 in each 100 of those engaged in trades with much dust, smoke, soot or vitiated air, except the stonecutters, of whom fully 50 per cent. of 151 were tuberculous. His statistics include 1,501 men and 851 women. Of this number 670, that is 382 men and 288 women, have been followed for a number of years. The course of tuberculosis was more prolonged in the women and in subjects engaged in indoor work, who are usually in better circumstances. Comparing these 670 cases with Weicker's 1,395 cases of pulmonary tuberculosis treated in the sanatoria, the results show that sanatorium treatment as at present conducted has prolonged by three years the working capacity of tuberculous subjects in the first or second stage of the disease in about a fifth to a fourth of the entire number. After the third or fourth year the mortality and loss of working capacity do not show the influence of the sanatorium treatment.

111 to 113. **Functional Kidney Tests.**—Israel warns against trusting too implicitly to the phloridzin and other functional tests which may impart a false sense of diagnostic security. The variations in the freezing-point and the phloridzin test frequently contradict each other, and repeated tests on the same person may give different results at different times. Rovsing ventured to remove a kidney in a case in which the phloridzin test was negative on both sides, and Israel has also done this twice, with complete success in all. The lack of any elimination of sugar does not necessarily indicate the loss of the physiologic functions in all cases. The freezing-point is not always invariable even in health, and has a wide range in varying circumstances in the same person.

114. **Psoriatic Arthropathy.**—Adrian applies this term to a multiple joint affection complicated with psoriasis and distinguished by its chronic course, the lack of influence of the salicylates and the frequent deformities and destruction of the joints which it may entail early. He has found records of 81 cases in the literature, and describes another personally observed. The patients were mostly males, usually between 40 and 45, affected with generalized psoriasis. No predisposing factor could be discovered in the histories except in a few isolated instances in which a central or reflex trophoneurosis might be incriminated. There was no evidence of an infectious character, except, possibly, the occurrence of exacerbations occasionally during the protracted course of the disease. No connection could be discovered between it and gout, gonorrhea or syphilis. Treatment should combat both the arthropathy and psoriasis and baths are beneficial for both. The mild forms with merely arthralgia are generally curable, but in the graver forms the prognosis is bad.

116. **Stenosis of Pylorus in Infants.**—Freund has been able to collect 10 cases of this condition in infants in which an operation was performed, with 7 permanent successes. Knöpfelmacher has published a case in which he discovered hyperchlorhydria with the stenosis and all symptoms permanently disappeared as soon as the child was put on whole milk. In others on record improvement was likewise obtained on change of diet. Freund has observed 6 cases, all breast nurslings. Case 1 was operated on, but soon succumbed, and the autopsy disclosed that the antecolic gastrojejunostomy and enteroanastomosis had been surgically successful, but ulcerations were found in the jejunum, the source of the fatal hemorrhages. In Case 2 the Günzburg reaction was always positive, and so soon as the child was taken from the breast and put on whole milk all disturbances ceased. In 2 of the children the stenosis proved rebellious to all internal measures and the children died. Another rapidly recovered when put on whole milk after cream had been removed, and in another the symptoms of stenosis vanished on administration of a tablespoonful of Carlsbad water before each meal. One of the children developed the stenosis while still under observation after birth, and it was unmistakably primary. Freund's experience indicates, therefore, that the stenosis is generally and most probably spastic. Carlsbad water should be given first and then whole milk, omitting the fat if necessary. If the weight still falls gastroenterostomy should be done without delay to allow the favorable moment to pass.

132 Plastic Reproduction of Stools in Gastrointestinal Affections. H. Roeder.—Die Einführung plastischer Lehrmittel in die Klinik der Magendarmkrankheiten.

117. **Tickling Reflex in Cerebral Affections.**—Pick describes a case in which a focus of softening corresponded with the hemiplegia observed and was also probably connected with the absence of the tickling plantar and axillary reflex on the side opposite to the focus. The latter was located in the frontal plane characterized by the corp. subthalam. The fibers involved were those connecting the thalamus and lenticular nucleus and these ganglia are the ones to which are referred the involuntary mimic movements and involuntary laughing. It is, therefore, logical to associate their degeneration with the absence of the tickling reflex. Pick thinks that this reflex has not heretofore been accorded the importance it deserves. Bleuler has reported a case in which symptoms of a cerebral lesion were accompanied by absence of the tickling reflex on the right side, and the left internal capsule was found diffusely degenerated. Bechterew also observed the absence of the tickling reflex in a cerebral affection, but without autopsy.

118. **Etiology of Progressive Paralysis.**—Raimann has been investigating this subject at v. Wagner's clinic, Vienna, along the lines suggested by Bruce and Robertson, that is, the theory that autointoxication from the digestive tract is the principal etiologic factor, and that the colon bacillus is involved in it to a large extent. Raimann's results were negative in so far as the agglutination reaction can be accepted as a test of the participation of the colon bacillus in the process.

119. **Operative Treatment of Suppurative Meningitis.**—Haberer describes a case of leptomeningitis involving the entire hemisphere of the brain in a woman of 36. The symptoms indicated a circumscribed process, secondary to a phlegmon of the temporal region, and, after first trephining, the skull and dura were opened up, but as far as the eye could reach there was the same suppurative inflammation. Each intervention was followed by marked abatement of the symptoms. The im-

provement in the general condition continued for two days after the last, but then the patient rapidly sank. The operations were performed by v. Eiselsberg and he is convinced that if he had been less cautious and had opened up the dura at first into sound tissue, it is possible that the patient might have recovered. He believes that the lesion was circumscribed at the time of the trephining and might have responded favorably to more thorough evacuation of the pus. Lumbar puncture after trephining was negative.

122. **Spastic Obstipation.**—Singer distinguishes between symptomatic and idiopathic spastic obstipation and defines the symptomatology of the latter and outlines the treatment. Purgatives and laxatives, even cascara, should be strictly forbidden, he states. The continuous use of saline purgatives is liable to increase the tendency to spasm, and especially courses of mineral waters. Mechanical procedures, massage and electricity are also contraindicated. Oil enemata are useful if taken warm enough. More permanent benefit can be derived from measures addressed to the nervous foundation of the trouble, particularly from hydrotherapy. The application of moist heat has proved very beneficial in his experience, a combination of a moist abdominal bandage and thermophore appliance. Hot cataplasms and sitz baths also have a favorable effect, but the sovereign remedy is belladonna, which he orders in the form of suppositories. His experience has been that the internal sphincter is usually the seat of the spasmodic contraction. For several years he has used English bougies, introduced into the rectum, when the constriction was in this region. He inserts the bougie in the knee-elbow position, sometimes preceding it with cocain or belladonna in case of very sensitive patients. It is occasionally impossible to pass it beyond the internal sphincter at first, but by leaving it for a time in contact with the sphincter it can then be readily passed through. Conical bougies meet with less resistance. The reaction is felt by the patient at first as a painful contraction and the bougie is held tight. In a few minutes the contraction subsides and the bougie can be twisted around. He begins with a small caliber and increases the size gradually. The results of this method of treatment have been so fine that he urgently recommends it to others for suitable cases. In a few instances he has found that the constriction vanished in the rectum but appeared higher up in the intestines. Generally the procedure, alone or associated with other measures, rapidly abolished the spasmodic contraction and induced defecation. Little can be anticipated from dietetic measures in spastic obstipation. On the other hand, change of scene, rest cures, relief from mental stress or worry and other means of reducing the nervous irritability will prove invaluable factors in the cure. Many persons who are constipated at home have no trouble in this respect when traveling. He states that in diagnosing the aspect of the stools is very important, especially the ribbon-like or grooved pencil-like forms. He has frequently noted blood in the stools, and in one case of enterospasm with kidney stone one of the attacks ended with the evacuation of a large amount of fresh and coagulated blood. There may also be strips of mucus. The contraction of the internal sphincter is the chief differentiating feature.

123. **Autointoxication as Cause of Uncontrollable Vomiting of Pregnancy.**—Dirmoser has long proclaimed this theory of the etiology and now reports a case in which a toxin was derived from the contents of the intestines so powerful that it killed the laboratory animals in three hours. Spontaneous premature delivery occurred at the height of the attack and the placenta was examined for a possible toxin, but animals inoculated with an extract of the placenta showed no signs of intoxication and remained as lively as before. The absence of a toxin in the placenta speaks against a fetal origin for the cause.

126. **Moser's Scarlet Fever Serum.**—This article describes the results of serum treatment at the Franz Josef Hospital at Vienna, and the writer joins the chorus of those who report marked benefit from its use. He reports the details of the 26 cases and emphasizes the mild course of streptococcus sepsis occurring two weeks after the injection, terminating in recovery. Out of 13 children considered moribund when received, 5 recovered after serum treatment, and 9 out of 12 with dubious to bad prognosis. The immediate results of the serum were always decline of temperature, diminished frequency of pulse and respiration, subsidence of delirium, tranquil sleep, the periphery grew warm and cyanosis disappeared. During the further course the necrotic patches became red, the fetor vanished partially or entirely and the children lost their very sick aspect. Even in the fatal cases there was always marked improvement after the injections.

128. **Saline Infusion in Treatment of Relapsing Fever.**—Karlinski noted that the addition of salt to a serum which agglutinated cultures of the parasite of relapsing fever immeasurably enhanced the agglutinating power. This suggested that salt might have a favorable effect on the course of the disease, and he reports the clinical application of this suggestion with results which apparently confirm the correctness of the assumption. In the epidemic of 890 cases he observed only 160 with but one attack, while 490 had two, 140 three, and 92 four. In his 5 cases treated by subcutaneous injection of 1,200 c.c. of a 1 per cent. saline solution in the course of forty-five minutes, none had a second attack, although the first had been very severe. He thinks it is possible that salt introduced into the system in some other way might prove equally effective.

129. **Early Diagnosis of Pleuritis Diaphragmatica.**—The character of the pains, the disturbance in the action of the diaphragm and a peculiar backward and energetic contraction of the upper portion of the abdominal rectus on one side, during inspiration, bringing into prominence the attachment of the muscle to the costal cartilage and the ensiform process, are the chief signs of this form of pleuritis, with distressing cough and considerable dyspnea. Stenitzer relates a case in which early differentiation of a serofibrinous pleuritis diaphragmatica was possible, and prompt treatment soon resulted in a cure free from complications. The pains are intense; they are located in the lower part of the thorax and radiate into the epigastrium, hypochondrium, etc., and especially into the sacrum and shoulder on the same side. The pain in the shoulder may be the first sign to suggest inflammation in the diaphragm. Mussy's "diaphragm point" was sensitive to pressure and also the phrenic nerve in the neck, in the 2 cases described. The high position of the diaphragm on the affected side was also striking, as likewise the abnormal excursions, the absence of transposition of the base of the lung during respiration, and also of Litten's diaphragm sign. Singultus has been frequently observed, but did not occur in Stenitzer's experience, except agonal in the one purulent fibrinous case.

131. **Retrograde Incarceration of Intestine.**—Langer reports a case which he qualifies as the first clinical case on record of "retrograde incarceration" of the intestine in which the mesentery of the intervening portion lay free in the abdominal cavity. Maydl has expressly denied the possibility of such an occurrence. The intra-abdominal complication induces local meteorism but no peristaltic movements in the region involved, and only an operation will reveal the two loops in the hernia. The intervening portion must be removed with the incarcerated loops as its blood supply will be impaired.

135. **Tuberculous Intestinal Stenosis.**—Nikolski reports a case personally observed and concludes from a study of the literature that this affection may cause gradually developing or suddenly acute symptoms or may run an entirely latent course. The clinical picture is that of dyspepsia or chronic diarrhea. It is most frequent between 20 and 40 and is usually secondary and located in the lower part of the ileum. Surgical intervention is the only treatment and should be prompt, with careful search for multiple strictures.

137. **Twenty-one Operated Cases of Extrauterine Pregnancy.**—Eberlin's patients all recovered. Laparotomy was done 15 times, colpotomy posterior twice, and incision of the posterior vault 4 times. The pregnancy was abdominal in one case, interstitial in another and tubal in 15, with hematocele in 4. The adnexa were removed on one side in 12 and on both sides in 2; uterus and adnexa in 1. He thinks that immediate laparotomy is required when the patient shows symptoms of what he calls "volcanic abortion," but when the volcano is merely smouldering, a favorable moment may be waited for, while a hematocele may be compared to an extinct volcano, the débris of which can be readily removed through an incision in the posterior vaginal vault.

141. **Malarial Affections of Air Passages.**—Coryza, cough, bronchitis and pleuritis have been observed in malarial districts, evidently due exclusively to the infection, as they were cured by quinin and were rebellious to other measures, including the usual expectorants. In the 4 cases described the first patient was a man of 46 with a severe, dry, spasmodic cough and malarial parasites in the blood, with a tendency to dyspnea and a sensation of oppression in the chest. The second patient complained of coryza, cough and fever, all the symptoms vanishing under quinin. The third patient presented symptoms of sudden pleuritis, vanishing with equal suddenness on exhibition of quinin. In the fourth patient the parenchyma of the lung was involved. These affections are observed most frequently in comparatively young persons residing in or recently arrived from malarial districts. The malarial coryza is distinguished by the marked variations in the morbid symptoms in the course of a single day. The nasal mucosa is red, dry and tender, or the symptoms may be those of hay fever. The cough is like a "nervous cough." The bronchitis may be catarrhal or "dry," the cough resembling that of pertussis. The diagnosis of the malarial origin is not difficult if the possibility occurs to the physician, and the rapid cure under quinin confirms it. Sverzhenski does not attribute these malarial manifestations to local toxic action but to the intermediation of the nervous system.

143. **Non-Malignant Intestinal Tumors in Children.**—Egiz reports a case of fibro-leiomyoma removed from the small intestine of a girl of 11. The tumor was rooted in the mucous membrane of the intestine and was the size of a mandarin orange. It developed without causing symptoms of constriction or occlusion and manifested its presence by giving rise to antiperistaltic movements, pains in the abdomen and vomiting two or three times a week for six months. There was occasional constipation, no fever, no tenderness. Nothing was found to explain the pains on an exploratory laparotomy, but as the antiperistaltic movements, pains and vomiting increased in intensity, minute palpation revealed a small tumor in the left side. A second laparotomy showed that the tumor originated in the mucosa of the small intestine, and it was easily removed. The little patient died four days later from septic peritonitis and the autopsy disclosed that there must have been invagination at the time the tumor was removed as a linear wound was found in the intestine a short distance above, evidently inflicted when the intestine was incised. Egiz reviews the literature on the subject of non-malignant growths in children's intestines, which may be of several varieties. In regard to polyps he states that in only 30, that is .01 per cent. of the 300,260 children admitted to the Olga Children's Hospital at Moscow, have polyps been found. No cases of benign tumors in the intestines in children have been reported in Russia, but he has found 6 cases mentioned in German literature. Pochhammer published the case of two brothers, one 15, the other 6 years of age, who recovered after ablation of an adenoma in the rectum of each. Clutton's patient was a child of 8 with a dermoid cyst in the sigmoid flexure. Hilter observed a case of adenoma in the submucous tissue of the ileo-cecal valve. The patient was a girl of 10, who died with symptoms of gastrointestinal catarrh. Buchwald has published a case of two large cysts in the mucosa of the small intestine which caused complete occlusion. The patient was a boy of 6 who died the day after the laparotomy. The largest diameters of the cysts were 17 and 10 cm. and the course of the case indicated that they must have been congenital.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology Chicago Post-Graduate Medical School. Volume V. Obstetrics. Edited by Reuben Peterson, A.B., M.D., Professor of Obstetrics and Gynecology University of Michigan. April, 1903. Cloth. Pp. 204. Price, $1.25 net. Chicago: The Year-Book Publishers.

A COMPLETE LIST OF THE DRUG STORES IN THE DISTRICT OF COLUMBIA. Arranged in Systematic Order for the Use of Traveling Men. By Fred T. Hafelfinger, 1110 Fourteenth St., N.W., Washington, D. C. Compiled from the Directory of 1903. Paper. Pp. 8. Price, $0.25.

THE ERRORS OF ACCOMMODATION AND REFRACTION OF THE EYE AND THEIR TREATMENT. A Handbook for Students. By Ernest Clarke, Fellow of the Royal College of Surgeons of England. Cloth. Pp. 225. Price, $1.75 net. New York: William Wood & Co. 1903.

THE REFRACTION OF THE EYE AND THE ANOMALIES OF THE OCULAR MUSCLES. By Kenneth Campbell, M.B., Edin., F.R.C.S. Eng., Surgeon to the Western Ophthalmic Hospital. Cloth. Pp. 214. Price, $1.75 net. New York: Wm. Wood & Co. 1903.

THE PRACTICAL DETAILS OF CATARACT EXTRACTION. By H. Herbert, F.R.C.S. Eng., Major, I.M.S., Professor of Ophthalmic Medicine and Surgery, Grant Medical College. Cloth. Pp. 109. Price, $1.25 net. New York: Wm. Wood & Co. 1903.

THE PHYSICIANS OF THE DISTRICT OF COLUMBIA. Arranged in Systematic Order for Detail Men. By Fred T. Hafelfinger, 1110 Fourteenth St., N.W., Washington, D. C. Compiled from the Directory of 1903. Paper. Pp. 21. Price, $1.00.

AMBULANCE WORK AND NURSING. A Handbook on First Aid to the Injured, with a Section on Nursing, etc. Profusely Illustrated. Cloth. Pp. 304. Price, $3.50 net. Chicago: W. T. Keener & Co.

HOW TO KEEP WELL. An Explanation of Modern Methods of Preventing Disease. By Floyd M. Crandall, M.D. Cloth. Pp. 511. Price, $1.50 net. New York: Doubleday, Page & Co. 1903.

New Patents.

Patents of interest to physicians, May 5 and 12:

727069. Atomizer. Carl Bomelsler, New York City.
726889. Artificial foot. George F. Ehrle, Milwaukee, Wis.
727344. Covered suppository and making same. David Genese, Baltimore.
727145. Sterilizing and packaging surgical absorbent dressing. Robert W. Johnson, New Brunswick, N. J.
727383. Joint for artificial limbs. Edward Koeber, Chicago.
727159. Catamenial bandage. Samuel P. Langdon, Philadelphia.
727467. Invalid bed. Walter C. Sennett, Portland, Me.
727570. Means for separating air from liquid in carbonating or other apparatus. Charles L. Bastian, Chicago.
728160. Hypodermic syringe. Thos. A. Chappell, Bronwood, Ga.
728091. Apparatus for forming tablets, etc. Emil Duhring, Berlin, Germany.
727949. Bed pan. Lena M. Hoffman, Philadelphia.
728112. Cabinet for eye-testing devices. John M. Johnston, Chicago.
727645. Dose indicator for medicine bottles. Norman S. Lea, Charleston, S. C.
728175. Dilating nozzle. Gustav Otto, Jersey City, N. J.
728003. Massage cup. Charles Pfanschmidt and J. Siefert, Chicago.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the two weeks ending May 23, 1903:

Ashburn, James K., contract surgeon, is granted leave of absence for one month from about May 1, 1903.

Barney, Charles N., first lieut. and asst.-surgeon, will proceed to Ft. Schuyler for duty.

Hartnett, Eugene H., first lieut. and asst.-surgeon, on his relief from duty at Ft. Columbus, will proceed to Key West Barracks, to relieve First Lieut. Charles N. Barney.

Lippincott, Henry, colonel and assistant surgeon-general, is granted leave of absence, to commence about June 1 for one month, with permission to apply for an extension of two months and fifteen days.

Pettyjohn, contract surgeon, is relieved from duty in the Department of the Columbia, and will proceed to his home, Augusta, Ga., for annulment of contract.

Reagles, James, contract surgeon, is relieved from duty at Ft. Snelling, and will proceed to Ft. Keogh for duty.

Roberts, D. M., contract surgeon, is granted leave of absence for one month from May 15, with permission to apply for an extension of two months.

Wall, Francis M., contract surgeon, is relieved from duty at Ft. Thomas, and will proceed to Columbus Barracks for duty, to relieve Contract Surgeon Harper Peddicord, who will proceed to Vancouver Barracks and report to the commanding general, Department of the Columbia, for assignment to duty in Alaska.

Wilcox, Timothy E., lieutenant-colonel and deputy surgeon-general, chief surgeon Department of the Columbia, will proceed to such posts of that department in Alaska as may be necessary on business pertaining to the sanitary and medical inspection thereof.

Bloombergh, Horace D., first lieut. and asst.-surgeon, is granted an extension of leave for one month.

Miller, J. E., contract surgeon, is granted leave for twenty-three days.

Pinkston, Omar W., contract surgeon, now at Kansas City, Mo., is relieved from further duty in the division of the Philippines and will proceed to Madison Barracks for duty.

Pease, F. D., contract surgeon, is granted an extension of leave to include June 30.

Rafter, John A., contract surgeon, is relieved from duty at Madison Barracks, to take effect on the arrival at that post of Contract Surgeon Omar W. Pinkston, and will then proceed to his home, West Winfield, N. Y., for annulment of contract.

Shepard, John L., first lieut. and asst.-surgeon, is relieved from further duty at Ft. Apache and will proceed to San Francisco, Cal., and report for assignment to duty at the U. S. General Hospital, Presidio.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending May 13:

Surgeon F. W. Wieber, granted sick leave for two months.

P. A. Surgeon L. Morris, ordered to the *Minneapolis*.

Asst.-Surgeon R. H. Michels, ordered to the Asiatic Station.

Asst.-Surgeon E. M. Brown, detached from the Naval Hospital, Norfolk, Va., and ordered to the Naval Hospital, Newport, R. I.

Asst.-Surgeon J. H. Holloway, ordered to the *Baltimore*.

Dr. A. J. Geiger, appointed asst.-surgeon, from May 6.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended May 21, 1903:

Assistant Surgeon-General G. T. Vaughan, detailed to represent the service at the meeting of the Association of Military Surgeons at Boston, May 20-21.

P. A. Surgeon J. C. Perry, to report at Washington, D. C.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence on account of sickness, for fourteen days from April 24.

Asst.-Surgeon R. L. Wilson, granted leave of absence for seven days from April 28, under provisions of Paragraph 191 of the regulations.

Asst.-Surgeon A. J. McLaughlin, granted leave of absence for two months from May 1.

Asst.-Surgeon W. K. Ward, granted leave of absence for three days from May 14, under provisions of Paragraph 191 of the regulations.

A. A. Surgeon C. B. Ford, granted leave of absence for fourteen days from June 3.

A. A. Surgeon A. C. Fraser, granted leave of absence for forty-five days, on account of sickness, from April 27.

A. A. Surgeon W. H. Marsh, granted leave of absence for seventeen days from May 8.

A. A. Surgeon W. O. Wetmore, granted extension of leave of absence for fourteen days from May 15.

A. A. Surgeon W. M. Wightman, granted leave of absence for three weeks from June 7.

A. A. Surgeon W. W. W. Wilson, granted leave of absence for fourteen days from May 14.

Pharmacist W. F. Schlaar, granted leave of absence for three days from May 10, under provisions of Paragraph 210 of the regulations.

BOARDS CONVENED.

Board convened at San Francisco, for physical examination of an officer of the Revenue Cutter Service. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; Asst.-Surgeon C. W. Vogel, recorder.

Board convened at Washington, D. C., May 25, for the physical examination of candidates for cadetship in the Revenue Cutter Service. Detail for the Board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon-General H. D. Geddings, recorder.

Board convened at Washington, D. C., June 15, for examination of candidates for admission as assistant surgeon in the service. Detail for the board: Assistant Surgeon-General G. T. Vaughan, Chairman; Surgeon C. T. Peckham; P. A. Surgeon H. S. Matthewson, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 23, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, May 3-16, 13 cases.

California: May 3-10, Los Angeles, 1 case; San Francisco, 4 cases.

Florida: May 8-16, Chipley, 9 cases; Jacksonville, 7 cases; Pensacola, 5 cases.

Georgia: Atlanta, May 6-20, 4 cases, 1 death.

Illinois: Belleville, May 11-18, 9 cases; Chicago, May 8-16, 8 cases, 1 death; Galesburg, May 8-16, 3 cases.

Indiana: Ellwood, May 10-17, 7 cases; Evansville, May 1-16, 6 cases; Indianapolis, May 8-16, 6 cases, 1 death; Kokomo, May 8-16, 1 case.

Iowa: Des Moines, May 8-16, 1 case.

Louisiana: New Orleans, May 8-16, 7 cases, 1 death.

Maryland: Baltimore, May 8-16, 7 cases.

Massachusetts: Lawrence, May 2-9, 1 case, 1 death (doubtful).

Michigan: May 8-16, Detroit, 33 cases; Grand Rapids, 2 cases; Port Huron, 1 case.

Minnesota: Winona, May 8-16, 2 cases.

Missouri: St. Louis, May 3-17, 17 cases.

Nebraska: Omaha, May 8-16, 1 case.

New Hampshire: May 8-16, Manchester, 1 case; Nashua, 1 case.

New York: Elmira, May 8-16, 1 case; Rochester, May 7-14, 2 cases.

Ohio: Ashtabula, May 8-16, 1 case, imported from Toledo; Dayton, May 2-16, 6 cases; Toledo, April 18-May 16, 31 cases, 1 death.

Pennsylvania: Pittsburg, May 2-16, 48 cases, 7 deaths; Philadelphia, May 8-16, 35 cases, 1 death.

South Carolina: Charleston, May 2-16, 1 case; Georgetown, May 20, 1 case.

Tennessee: Memphis, May 8-16, 3 cases.

Utah: Salt Lake City, May 8-16, 5 cases, 1 imported.

Washington, Tacoma, May 4-11, 2 cases.

Wisconsin: Milwaukee, May 8-16, 3 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, March 21-April 4, 11 cases, 2 deaths.

SMALLPOX—FOREIGN.

Austria: Prague, April 18-May 2, 11 cases.

Belgium: Antwerp, April 18-May 2, 6 cases; Brussels, April 25-May 2, 4 deaths.

Brazil: Rio de Janiero, April 19-26, 2 deaths.

British Guiana: Demerara, April 25, present and spreading rapidly.

Canada: Quebec, March 2-9, 2 cases.

China: Hongkong, March 26-April 3, 4 cases, 1 death.

Colombia: Bocas del Toro, April 28-May 5, 1 death.

France: Paris, May 1-8, 1 death.

Great Britain: Birmingham: April 25-May 2, 5 cases; Bristol, April 25-May 2, 3 cases; Dublin, April 30-May 7, 23 cases, 3 deaths; Leeds, April 25-May 2, 14 cases; Liverpool, April 25-May 2, 69 cases, 4 deaths; Manchester, April 18-May 2, 17 cases; Newcastle-on-Tyne, April 25-May 2, 1 case; Nottingham, April 18-May 2, 2 cases; Sheffield, April 18-May 2, 6 cases, 2 deaths; Sunderland, April 25-May 2, 1 case.

India: Bombay, April 14-21, 73 deaths.

Italy: Milan, March 1-31, 1 case; Palermo, April 25-May 2, 1 death.

Japan: Kobe, March 27-April 11, 3 cases.

Mexico: City of Mexico, April 26-May 3, 7 cases, 10 deaths.

Russia: Moscow, April 18-25, 5 cases, 1 death; Odessa, April 19-May 2, 4 cases, 1 death; St. Petersburg, April 4-25, 58 cases, 12 deaths; Warsaw, April 11-18, 3 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, April 12-26, 34 deaths.

Colombia: Panama, May 7-14, 3 cases, 1 death.

Mexico: City of Mexico, April 26-May 3, 1 death; Tampico, May 8-16, 1 case, 1 death; Vera Cruz, May 2-16, 11 cases, 5 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, March 21-28, 1 case, 1 death. Provinces, March 21-28, 164 cases, 93 deaths; not previously reported, 14 cases, 14 deaths; March 28-April 4, 201 cases, 141 deaths; not previously reported, 521 cases, 261 deaths; April 4-11, 64 cases, 35 deaths; not previously reported, 547 cases, 291 deaths.

CHOLERA.

Straits Settlements: Singapore, March 21-April 4, 13 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, May 10, 1 death.

Philippine Islands: Manila, March 21-28, 6 deaths; March 28-April 4, 6 cases, 6 deaths.

PLAGUE—FOREIGN.

Australia: Brisbane, Feb. 1-28, 5 cases, 2 deaths.

Brazil: Rio de Janeiro, April 12-26, 1 death.

China: Hongkong, March 27-April 3, 28 cases, 24 deaths.

India: Bombay, April 14-21, 1,320 deaths; Karachi, April 4-19, 372 cases, 340 deaths.

Mexico: Mazatlan, May 14, 1 case.

The Journal of the
American Medical Association

Vol. XL. CHICAGO, ILLINOIS, JUNE 13, 1903. No. 24.

Address.

THE MODERN CONCEPTION OF ECZEMA.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON CUTANEOUS MEDICINE AND SURGERY AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT NEW ORLEANS, MAY 5 TO 8, 1903.

J. A. FORDYCE, M.D.
NEW YORK.

In comparing the views of modern dermatologists as to the types of inflammation of the skin which should be classed as eczemas, one is met with the most discordant opinions. Hebra undoubtedly accomplished a great service for dermatology in simplifying its nomenclature. His enormous clinical experience and power of observation enabled him to recognize that conditions which had before his time been called distinct diseases were in reality but different stages or phases of the same affection.

The modern tendency seems to be to break away from the extreme view of Hebra that all superficial catarrhal inflammations of the skin caused by irritants are eczemas. We are told that when the cause is known or apparent the inflammation is a dermatitis; when it can not be ascertained it is an eczema. If every one reacted in the same manner to irritants or if the effect always ceased with the removal of the cause the foregoing statements might appear less artificial. We know, however, that certain individuals are extremely susceptible to chemical, thermal or other irritants, while others show little or no reaction, even when they are applied in a more concentrated form or after prolonged exposure to them.

It is evident, therefore, that individual reaction, susceptibility or idiosyncrasy play an important rôle in the evolution of such inflammations.

Furthermore, a dermatitis from an external irritant may spread marginally, develop secondary patches or become generalized after the local irritant is removed. We can not, therefore, accept unreservedly the arbitrary definition that a dermatitis is the result of an external irritant, while an eczema is produced by some mysterious disturbance of metabolism.

It is often convenient, however, for purposes of instruction, to call an inflammation of the skin a dermatitis when its etiology is evident and it is sharply localized to the part where the irritant is applied. The more carefully we study our cases of superficial inflammation of the skin even when the cause is not at first apparent, the more convinced we become that the great majority of such cases are produced by the local action of some irritant which may be of chemical or microbic nature.

In either the so-called dermatitis, of which the cause is apparent, or in eczema, where we can not determine the etiologic factors, the clinical picture may be the same.

In both we have a superficial inflammation which is characterized by changes in the epidermis and papillary portion of the derma.

The intercellular edema, the parakeratosis, the vesicle-formation with resulting crusting and scaling, are common changes in both conditions. Why, then, should we employ such an artificial distinction as that used by many modern dermatologists, and say that here is a dermatitis because the involved skin has been subjected to a known irritant, and there an eczema because no local source of irritation can be found?

All the phenomena of inflammation can be experimentally produced by chemical or thermal agents under suitable conditions. The vascular dilatation, serous exudation, the migration of leucocytes with resulting changes in the epidermis and corium are found in a dermatitis from external irritants as well as in a so-called eczema of which the cause is not so evident.

If our clinical and pathologic pictures are the same, it would appear unscientific and unwise to insist on such artificial distinctions, except possibly as a clinical guide in the prophylaxis and treatment of such conditions. If we observe simply the objective features of a dermatitis without regard to its localization or its possible relationship to its bearer's occupation, it is difficult or impossible to say in what manner it differs from a so-called idiopathic inflammation of the skin.

A dermatitis excited by poison ivy may differ in no essential regard from an acute vesicular eczema of unknown origin.

We have all seen recurring vesicular inflammations of the skin in individuals who had at one time been the subjects of poisoning with this plant.

Are such eruptions due to the retention in the skin of the chemical poison of the rhus toxicodendron, to a new infection from the plant, or are they so-called idiopathic eczemas in a vulnerable patient?

In some cases we can with almost absolute certainty exclude a new infection from the plant, but the reaction of the skin in both cases may be exactly the same. It does not always, therefore, appear practicable to classify catarrhal inflammations of the skin from a strictly etiologic point of view. If we admit that catarrhal inflammations of the skin from local irritants differ in no essential feature from other catarrhal inflammations of the skin in which the etiology is not clear, we have a good reason for assuming that all such conditions may have a local cause; or at least we may say that there is as good reason for supposing that they are all local as for the other assumption that some may be constitutional.

We can not deny the possibility that eczema may be caused by some internal condition such as an infection from the gastro-intestinal canal or some disturbance in metabolism. It is unfortunately not possible to prove or disprove such a proposition. The view which is so widely held that eczema is a manifestation of the uric acid diathesis is equally vague and unsatisfactory.

All such general conditions which have been invoked to explain the occurrence of eczema may act as contributing factors in preparing the skin for the direct action of a micro-organism or its toxic products. This view is a rational one in the light of our knowledge regarding the pathogenesis of catarrhal inflammations of the skin of which the cause is known. The vessels of the papillary region react to irritants in the epidermis by dilatation and the outpouring of serum and leucocytes. The serum with its contained leucocytes is attracted to the irritating substance producing the phenomena to which we give the name of dermatitis or eczema. If the cause be a chemical or non-microbic one the dermatitis may cease with its removal.

If primarily microbic or if an infection be superadded the eruption may spread marginally or infect outlying or distant areas of the skin. It does not seem wise, therefore, to attempt to differentiate too sharply the so-called external types of eczema from the ones of which the cause is not at first apparent, for they may have identical clinical and histological features.

The wider our clinical experiences the more liable are we to find deviations from the typical varieties of eczema. We not infrequently see inflammations spreading from the scalp to the ears, face and upper portions of the body where no antecedent seborrheic dermatitis of the scalp existed. The scalp in individuals of uncleanly habits affords an excellent habitat for micro-organisms which, under favorable conditions, excite a spreading dermatitis. All eczemas which originate in the scalp are therefore not necessarily of the seborrheic type described by Unna. On the other hand, seborrheic dermatitis may originate on parts of the body far removed from the scalp and apparently independent of this source of infection.

In a general way we may divide and subdivide inflammations of the skin according to their etiology, site, clinical forms, etc., but we are constantly meeting with cases which are atypical in all of these respects.

The less definite our experience and knowledge, the more inclined are we to overestimate the importance of general conditions and neglect the causes which are apparent.

It is easy to say that eczemas are produced or modified by gouty states, indigestion or some indefinite general disturbance, but the more closely we study our cases in the light of modern knowledge as to possible sources of infection the fewer cases are met with which can not be better explained by some local toxic or microbic irritant. The majority of modern dermatologists admit that parasitic eczemas are met with which can not be differentiated from those of unknown causation. It would not seem possible in all cases or even in the majority of our skin inflammations to say that we can differentiate either by clinical or histologic features those caused by external irritants from the rarer forms in which the etiologic factor is not evident.

Admitting as we must, that the real cause in most of such inflammations is a local one, we should not overlook the importance of general conditions as contributing influences.

Patients suffering with nephritis or glycosuria, as we all know, are easily infected with pyogenic or other organisms. Alterations in the body fluids or tissues in these conditions render them favorable culture media for micro-organisms, consequently we are more apt to meet with erysipelas, boils or carbuncles in such individuals than in healthy ones. For the same reason chronic gastro-intestinal toxemia, anemia or gouty states may render the individual more vulnerable to the agent or agents which excite eczema.

We might with almost as good reason attribute erysipelas, furunculosis or other local infections to nephritis and glycosuria as to say that eczema is only due to such general causes as imperfect metabolism, gout or other morbid conditions.

In other words, if we claim for eczema a cause that must have its seat in the skin, the tissues are prepared for its action by a lowering of their resisting power.

This may be brought about, as we know from a consideration of other infectious processes, by purely local changes, or by some alteration in the fluids of the body.

Following inflammation of the epidermis and papillary body there is a remarkable increase in the irritability of the skin, which manifests itself by itching and other paresthesias. If irritants are applied to such an inflamed surface the morbid processes may be heightened and new centers of infection arise.

The development of such outlying patches have been explained by reflex irritation of the vasomotor centers.

For this and other reasons the nervous system has been supposed to play an active rôle in the evolution of eczema, and all causes which weaken the neuro-vascular tone are believed to render the individual more vulnerable.

Kromayer[1] attributes such importance to the irritability of the skin that he defines eczema as an atypical inflammation which is both the result and cause of an abnormal excitability of this organ.

Crocker,[2] because of the symmetrical outbreak of the disease and the involvement of definite vasomotor areas, is inclined to the belief that the nervous system is concerned in certain of its manifestations.

The symmetry of an eruption is by no means positive proof of the influence of the nervous system or of the constitutional origin of the malady. Scabies is a symmetrical affection, as are also certain eruptions from the local action of drugs or chemical irritants. A dermatitis excited by iodoform or arnica in a susceptible subject may rapidly spread and become symmetrical. It has been assumed in such cases that the outbreak on distant parts of the body is due to absorption and dissemination of the drug through the blood stream or through irritation of the vasomotor centers.

The latter hypothesis has been controverted by Csillag,[3] who has shown by experiments that when an irritant like arnica is limited to a certain spot its action is confined there. If a dermatitis appears on other parts of the body it is due to the accidental transference of the drug to that region.

The conclusions drawn from clinical observation are by no means free from errors, as witness the thousand and one causes which have been invoked to explain the affection in question, and which are largely the reflection of the views regarding pathologic problems prevalent at the time.

Eczemas follow or are associated with some general condition, therefore they are directly due to such a state;

they appear after a depressing mental emotion or shock, consequently the nervous system is concerned in their etiology. Such loose methods of reasoning lead us nowhere and serve only to confuse the problem. We have no experimental methods which can be employed to prove or deny such hypotheses, so that little progress is made by their elaboration.

Clearer ideas regarding the pathogenesis of eczema have been obtained by investigating the types of eruption which are now included in the eczema group. We have in this way gained a fairly well-defined clinical conception of seborrheic eczema and various forms of infectious dermatitis produced by staphylococcus and streptococcus inoculation.

In our search for a local cause in eczema we should by no means minimize the importance of all conditions, both general and local, which favor infection. In hospital and dispensary practice, where less attention is paid to cleanliness, infectious forms of dermatitis are more frequently met with. Among well-to-do patients metabolic disturbances may deserve more attention.

It is perhaps also well to bear in mind the manner in which different individuals react to irritants. After the ingestion of the iodids one person may develop an erythema or urticaria, another a pustular or bullous eruption, a third cutaneous or subcutaneous nodules. Rashes of similar or identical appearance may be called forth by a great variety of drugs.

Brocq,[4] from a consideration of these phenomena, has classified eruptions like urticaria, the erythemata, prurigo, lichen planus and vesicular eczema, as pure cutaneous reactions. His conception of such dermatoses is that they have no precise etiology but may be evoked by a variety of external or internal irritants.

The individual reaction or idiosyncrasy may, therefore, be added to the other general conditions which favor the development of an eruption or determine its type. It is impossible with our present knowledge to frame a single hypothesis which will explain in a satisfactory way the clinical group of inflammations that we are accustomed to class as eczema. The difficulty is further increased by the divergence of opinion as to what constitutes the disease. In Brocq's conception of eczema as a pure cutaneous reaction, he considers only the vesicular type. We have, however, forms of cutaneous catarrh, in which the vesicle does not appear, but where we find under the microscope the same vascular and epithelial changes which exist in certain stages of vesicular eczema. The agent which provokes the outpouring of serum may in one case have such a slight chemiotactic influence as only to give rise to an epithelial edema which stops short of vesicle formation.

The serotactic power of the irritant, on the other hand, may be so intense as to elevate large areas of the stratum corneum. Between these two extremes all grades of epithelial edema may be found, producing slight redness with scaling, vesiculation or large oozing surfaces. The same irritant acting on different individuals may give rise to a vesicular eruption, a scaling erythema or a most intense eczema madidans. It does not seem logical, therefore, to limit our definition of the affection, either from a clinical or histologic standpoint, to a purely vesicular eruption. The nature of the irritant as well as the resisting power of the tissues determines the gross appearance of the eruption.

Brocq's contention that true vesicular eczema should be classed with urticaria, the lichens, etc., as a pure cutaneous reaction, is rather a one-sided view of the question. The nature of the irritant is certainly of equal importance, though we may not be able to maintain with Unna that eczema is a distinct morbid entity always due to a specific agent.

LICHENIFICATION OF THE SKIN.

Little or no attention has been given by dermatologists in this country or England to the endeavors made by Vidal, Brocq and Jacquet and other members of the modern French school to differentiate the condition described by them as lichen simplex, lichenification or *névrodermite* from chronic eczema on the one hand, or lichen planus on the other.

Brocq in numerous contributions to periodical literature and in his article on the lichens[5] contends in a forcible way for the recognition of an independent dermatosis which is met with about the joints, back of the neck, inner aspect of the thighs, and other parts of the body. The condition in question occurs in neurotic subjects and first manifests itself as an obstinate pruritus. Under the influence of scratching the skin becomes altered in color, slightly thickened with deepening of its normal lines and the seat of numerous closely aggregated flat papules of a dull red color.

The papules are less well defined than those of lichen planus and have neither their polygonal outline nor their central umbilication.

Transitional forms are met with which are somewhat difficult to differentiate, but the two eruptions have quite characteristic features which enable them to be recognized by the expert diagnostician.

Névrodermite or lichenification is distinguished from chronic eczema by its peculiar manner of evolution and the absence of vesiculation or crusts. It is always preceded by localized itching and preserves an absolute dryness throughout its course. It is chronic, rebellious to treatment, and tends to relapse.

Lichenification may develop about a patch of chronic eczema, a lichen planus or other dermatoses and thus obscure the underlying condition. The clinical description of the affection with the details of diagnosis are fully considered in Brocq's[5] article and strongly support his contention that the dermatosis deserves a distinct place in dermatologic nomenclature. It is at least descriptive of a clinical condition which can in a certain number of cases be distinguished from lichen planus and chronic circumscribed eczema. In doubtful eruptions an examination of the oral mucous membrane will sometimes determine the diagnosis, for in this region lichen planus presents quite characteristic changes.

The writer has recently had under his care two cases of chronic thickening of the skin with hypertrophy of the horny layer involving the entire cutaneous surface. In both cases intense pruritus was present. Over the extensor surfaces of the joints, the gluteal folds and elsewhere the skin presented typical lichenification. No moist lesions were present in either case, nor was there any development of lichen papules. The histologic changes consisted of a chronic inflammation of the derma with a moderate acanthosis and marked hypertrophy of the stratum corneum.

The conditions described could neither be called chronic eczema nor lichen planus, but corresponded in all details with Brocq's generalized *névrodermite.*

STREPTOGENETIC AND STAPHYLOGENETIC DERMATITIS.

There is little doubt, in the light of modern clinical and bacteriologic research that many types of catarrhal inflammation of the skin which were formerly called

MERCURIAL TREATMENT OF SYPHILIS.

A FURTHER CONTRIBUTION TO THE STUDY OF MERCURIAL INJECTIONS.*

M. L. HEIDINGSFELD, M.D.
CINCINNATI.

In the light of our present knowledge, success in the treatment of syphilis (at least in its earlier stages), is in direct proportion to the amount of mercury which the infected system can readily assimilate, without insult and injury. This knowledge, though purely empirical, has been so clearly and conclusively established, by centuries of observation and study, that it has become one of the most evident and acceptable of medical facts and so complete and successful have been the achievements of mercury in this direction that the experiments with serum therapy and the efforts to substitute other measures have been entirely devoid of practical results and have gained for themselves simply scientific interest.

Any shortcomings in its therapeutic powers must be imputed, in very large measure, to technical imperfections in its administration, and whatever definite progress syphilitic therapy has made has been along the lines of improved technical administration. That the administration of mercury has not been devoid of technical imperfections is clearly evident, not only from the various methods which have been employed for its successful administrations: through the skin, lungs, blood and lymph circulation and intestinal tract, but also because it has been used in innumerable simple and combined forms. It is equally evident that the technical imperfections, whatever their nature, were not of a character to impair the unqualified power and efficacy of mercury against the disease, but induced minor disturbances, purely secondary in nature, such as inconvenient or difficult administration, inaccurate dosage, and injury or insult to the organ, skin, lungs or intestinal tract against which it was particularly directed. The older forms, both inunctions and intestinal administration, have proven to be eminently reliable and efficacious, as far as checking the ravages of the disease is concerned. When failure has attended either of these forms of administration, non-success could usually be attributed to such causes as too excessive or too prolonged treatment or some grave form of complication. Efforts, therefore, to substitute methods and preparations were instituted more for the purpose of overcoming objections in technic than to achieve any great advance in efficacious action.

The oldest method, that of inunction, is objectionable because it is decidedly uncleanly, not only because a dirty ointment is rubbed freely over the body and frequent bathing is precluded, but because it soils the underclothing and bed clothes. It courts comment and publicity, predisposes an artificial dermatitis, is contraindicated in hairy individuals, and without the aid of an attendant is applied with some difficulty. Many of these objections are obviated by the wearing of mercurialized cloth (Blaschko[1]), or sacks filled with the remedy (Welander[2]), but neither of these methods have been demonstrated to be sufficiently active or reliable to merit special consideration; moreover, mercury being a volatile substance, these various methods are essentially an inhalation method of treatment, and as such are strongly contraindicated in hemoptysis and phthisis, which is also a serious objection to vaporization treatment (calomel fumes, etc.) in every form.

The internal treatment predisposes gastrointestinal disturbance, which is often sufficient to distress the patient, impair digestion, induce loss of weight, and thereby exert debilitating influences of considerable moment to the infected patient. The substitution of a long list of mercurial remedies for the pill mass, gray powder, bichlorid and calomel, in the form of biniodid, protoiodid, tannate of mercury, etc., and a more carefully regulated dosage, has been for the purpose of circumventing these objections, but has been attended with only partial success; moreover, whatever mercury is assimilated by internal treatment is carried directly to the liver, on which it not only exerts a deleterious influence but is in turn subjected to the altering, filtrating and eliminating action of the liver. Both inunctions and internal administrations are inaccurate methods, and it is impossible to determine how much or how little mercury is being assimilated in any given case. This is particularly true in internal treatment, when gastrointestinal symptoms supervene, a goodly portion of the mercury being prematurely carried away by the free discharges. Inspissated gelatin-coated pills or too strongly compressed tablets may not be assimilated and pass through the intestinal tract in unchanged form. Both the inunction and the internal method of treatment permit the patient to indefinitely continue, renew or discontinue treatment in accordance with his own volition, and thereby remove him from the regulating attention and vigilance of his physician which, in a disease prone to exacerbations, recurrences and grave complications, and accompanied by manifestations which are oftentimes overlooked or mistaken for other forms of affection, is a matter of most serious importance.

Most of these objections are entirely obviated by the injection method of treatment, and when Hunter and Hill[3] in 1856, Hebra[4] in 1864, and Scarenzio[5] in 1865, instituted mercurial injections, a new era in syphilitic therapy was marked. These investigations, on account of their severe painful character, were short lived and would have doubtless remained obscure had not Lewin[6] aroused new and well-sustained interest by his investigations in 1868, which were promptly confirmed by Sigmund[7] and Zeissl.[8] The injection method, though free from the many objections of the other methods, has not been entirely devoid of imperfections. Many of the attempts to employ this method have been short lived, and have gained for themselves a vast amount of unfavorable criticism. The innumerable forms of mercury which have been employed for injection purposes, metallic, bichlorid, calomel, yellow oxid, salicylate, sozoiodol, foramid, succinimid, bicyanid, glycocol, aspargin, alamin, thymolo-aceticum, and every form of combination, albuminates, peptonate, benzoates, suspensions in mucilage, oil of vaselin, paraffin, olive oil, lanolin, oil of sweet almonds, etc., bear abundant evidence that these imperfections not only exist but that their solution lies in an improved technic.

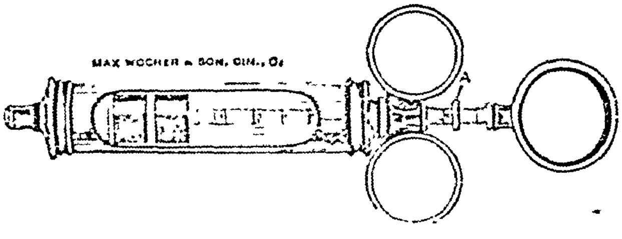
Time and space will not permit a careful consideration of the various causes of the non-success of the various preparations and methods which have been employed for injections; it will suffice to state that the most potent factors in their unsuccessful administrations have been too small and too oft-repeated dosage, which is too expensive and too time-consuming for the average patient; too severe and painful reaction, even to the degree of abscess formation; unstable character and difficult preparation of the remedy; danger of embolism and other grave forms of complication following its administration. A preparation which obviates these objections more successfully, I believe, than others has been the oleum cinereum, or gray oil after the formula of Lang.[9] In a preliminary report read before the Ohio State Medical Society and published in THE JOURNAL[10] of the American Medical Association, the marked advantages of this preparation in modified form, consisting of 3 to 4 parts of mercury to 1 part of lanolin, with just sufficient liquid albolene to render the preparation thin enough for injection purposes, were demonstrated from a series of 2,000 injections covering 240 cases of syphilis in clinical and private practice. Although intolerance was manifested in about 10 per cent. of the cases and the preparation did not possess the full desired degree of stability, I was so favorably impressed with its general excellence that I have continued to use it, as far as practical, to the exclusion of every other form of treatment. Subsequent study and experience has led me to make a few additional modifications, which have obviated the few remaining objections, and have placed it in such a perfected state that I am firmly impressed that it bids fair to ultimately supplant all other forms of treatment.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, W. L. Baum and J. A. Fordyce.

These changes, and the causes which prompted their consummation, are as follows: In the 2,000 or more injections which were made with the original formula, although Lesser's[11] precaution to remove the syringe from the needle after its deep insertion, in order to test for hemorrhage, had not been observed, not the slightest symptom of embolism, in the form of syncope, cough, pain in the chest, dyspnea, etc., as first observed by Lesser[12] (1 case), and subsequently Lesser[13] (2 cases), Quincke[14] (7 cases), Lindstrom[15] (2 cases), Oedmansson[16] (12 cases), Blaschko[17] (3 cases), Möller[18] (28 cases), and innumerable others was ever noted. Inasmuch as the frequency of embolism, following injections, varies considerably with the experience of different investigators, Möller,[18] for example, has observed it 28 times in 3,835 injections, Neisser[19] once in 800, Epstein[20] 7 times in 8,292, and Harttung[21] but once in 8,000 injections, it can be seriously questioned on the one hand how carefully the symptoms have been observed and interpreted, and on the other how inadvertently overlooked. These facts did not inspire me with such confidence as to not take prompt cognizance of a symptom of such grave nature, however slight in character, and when J. S., aged 29 years, infected himself with syphilis in January, 1902, and underwent a course of mercurial injections in February and March and a second course in July and August, presented himself on Nov. 7, 1902, seven days after he had received the twelfth injection of the third course of injections, instituted Sept. 23, 1902, with a well-marked left-sided facial paralysis, my fears for an untoward result were momentarily, at least, realized. My fear was intensified at this juncture by Dr. Gilbert Bailey, who reported to me that E. P. M., whom I had seen with him in consultation, Oct. 29, 1901, relative to a very grave infection of syphilis which baffled all ordinary measures and whom a course of injections, at that time very materially benefited and for whom he had just administered a subsequent course of injections, had been suddenly seized with a paraplegia of the lower extremities while en route to New York. One physician out of three who had seen the case in consultation in New York City ascribed the paraplegia to the injections, the remaining two, however, dissented from this opinion. Although the symptoms manifested in neither case could be attributed to the injection, the first was a Bell's paralysis, due to a severe cold from which the patient was at that time suffering, as clearly demonstrated by means of immediate tests, and its very brief and uneventful course; the possibility of such an occurrence prompted me to eliminate as much of the danger as circumstances would permit.

The danger of embolism was all the more forcibly impressed on me at this time by some work in paraffin prosthesis which I was pursuing after the method of Gersuny,[22] and particularly by reports of embolism by Pfannenstiel[22] and others, in their experience with paraffin prosthesis. The mineral nature and exceedingly stable character of paraffin and its closely allied product, liquid albolene, which, by reason of its more fluid character, predisposes all the more strongly to embolism when injected subcutaneously, would impart not only antagonistic properties to any area where it would, perchance, find an unfavorable lodgement, but its future disintegration, absorption, elimination and removal would be definitely precluded, according to the interesting and carefully conducted experiments of Juckoff,[24] Hans Meyer,[25] et al., and the lesion would become more or less permanent in character. My prosthetic experiments also demonstrated that paraffin was more or less of a local irritant, and I attributed what little reaction my former mercurial injections induced, which was sufficient in about 10 per cent. of the cases treated, to warrant a change to some other form of treatment, in large measure directly to the liquid albolene.



I therefore determined to make the injections without incorporating liquid albolene, which has been accomplished, with every indication of complete success, for the past six months, according to the following formula and technic:

℞. Hydrargyri bidistill.*
Lanolin (Liebreich), āā 120
Conteratur usque ad perfectissimum extinctionem hydrargyri

Sig.: Inject one to three minims (deep gluteal or subcutaneous interscapular) twice weekly.

This preparation has the consistency of ordinary lanolin, and should be gently heated to about 100 F. before it is drawn into the open glass barrel of a hypodermic syringe. Great care should be exercised to carefully exclude all the air from the properly filled barrel; the syringe is then adjusted and armed with a 7/8 inch 22 gauge needle, the retaining screw (Fig. 1, A) run down, by which successive 1 to 3 minim doses are measured off for subsequent injections. If the preparation in the syringe is maintained at a temperature of 80 to 90 F. an ordinary 20 minim glass barrel syringe can be employed, otherwise an extra heavy syringe—an ordinary dental obtunding syringe (Fig. 1) answers admirably—should be used in order to withstand the pressure.

---

* Bidistilled mercury, same as dentists employ for the manufacture of amalgams, should be used, which can be readily incorporated into an equal amount, by weight, of lanolin, in a few moments, by rubbing them togethed in a clean mortar, under ordinary aseptic precautions.

This preparation possesses perfect stability at all ordinary temperatures and insures the greatest degree of tolerance; although the remedy has been used, as far as practical, to the exclusion of every other form of treatment, and a thousand injections have, approximately, already been made, there has been relatively little localized reaction and induration and the patients take such little note of subjective pain or distress that they generally can not remember whether the last injection was made in the right or left buttock. A change to some other form of treatment has not been indicated in a single instance. Its semi-solid character (at 50 F. it can be expressed from the syringe in the form of a molded filament) minimizes the little danger that exists from embolism, and it is of such a nature that its complete absorption and elimination is ultimately assured.

The injection should be preferably made deep into the buttocks, perpendicularly to the surface of the skin, at its most prominent aspect, at three to four-day intervals, until 12 to 15 injections have been administered. The initial dose should contain about 1 minim, which can be gradually increased to 2 or even 3 minims (1 to 2 grains or more of metallic mercury to each injection). By this method relatively ten times more mercury is administered with each injection than with regulation 15 to 20 minims of the 1 per cent. bichlorid, foramid or succinimid solutions, and practically twice as much as the regulation injections of calomel, salicylate, thymoloacetate and yellow oxid injections.

In women the injections can be made interscapular, subcutaneously, and, though they are well tolerated, they are usually attended by a slight degree of reaction, owing to their more superficial deposition.

There is no plugging of the needles from the use of this preparation, which is an objection which has been raised against the use of insoluble injections (Bayet[26]). My personal experience impresses me that there is no indication for a progressive decreased dose or gradually prolonged intervals between injections, as urged by Ullmann,[27] Lang,[28] et al., in order to prevent accumlative effects and consequent unfavorable action in ptyalism, mercurial nephritis and allied complications. Mercurial stomatitis was avoided by exercising good care of the teeth, as far as practical; but when it did ensue, in a few instances, as it is frequently wont to occur, especially in clinical practice, its course was scarcely more severe or intractable than when it results from other forms of treatment.

In recent infections the injections were instituted with the appearance of the roseola, in accordance with the well-sustained views of Düring,[29] Taylor[30] and Watrezewski[31]: three courses of injections of 15 each are administered at four-month intervals the first year, two at six-month intervals the second year, one the third and one every two or three years thereafter.

Although the clinical results following the use of this preparation have been uniformly good, and the cases without exception showed prompt and marked improvement, not only in point of rapid amelioration of symptoms, but also in appetite, color and activity, followed by a state of well being that persists for many months after treatment is suspended, the good effects derived from this method do not differ materially, I believe, from those of other methods of treatment. It is simply the assimilated mercury which is effective in all cases and when non-success attends its administration it is due to such causes as faulty assimilation or its deleterious influences on the important organs or the system at large. In the injection treatment mercury is placed where it will do the greatest amount of good with the least deleterious effect, and the other natural advantages, in the way of cleanliness, control of patient, accurate dosage, should justly render it the ideal and popular method of treatment. The obstacles which have heretofore defeated this realization, intolerance, small and oft-repeated dosage, instability, difficult preparation and administration and distressing complications, no longer attain in this new form of treatment.

DISCUSSION.

DR. A. H. OHMANN-DUMESNIL, St. Louis—I am very much interested in the hypodermic treatment of syphilis because nowadays I confine almost my entire treatment to that method. I have better control of the patient and the dose of mercury he receives and the regularity with which it is received. I have been in the habit of using a solution of bicyanid of mercury and have never seen any untoward symptoms from its use. In over fifty thousand injections I have never seen a purulent complication. That is easily understood as the bicyanid of mercury is antiseptic. There is no particular pain, although when the solution is strong there may be pain lasting an hour or so, then it disappears. I think it is a good sign of lack of pain in the subjective symptoms when the patient comes back regularly for his injections. I put the patient through a course of from twenty to forty days, then give him a rest of fifteen or twenty days, then give him another course. With that method I have had the pleasure of seeing very good results. In some cases that were old, where there was a right hemiplegia, the paralysis disappears entirely, instead of having paralysis caused by the injections. Cases of syphilitic insanity give way in four or five weeks. In alcoholics and patients with homicidal impulses these symptoms disappear, and I have had patients under observation for five or six years who still remain clear in intellect and with no other symptoms manifest. Judging from these results the hypodermic method of treating syphilis seems to be successful—no untoward symptoms, good final symptoms and progressive improvement. I hardly think any other method could do as well. I agree with the reader that mercurial inunctions are dirty and not always adapted to the case. In Germany you can make these inunctions, the patient will go through his course, and in Hot Springs, Ark., you give him 25 packets, one to be rubbed in daily, and he takes a hot bath to eliminate the mercury, but you see him later on with rheumatism. You would not dare to predict a complete cure from a few injections, but they will predict cures from a few inunctions, which is not true, and if you read the reports they all publish you will find a number of relapses occur, and the treatment is begun again.

Dr. J. B. Kessler, Iowa City, Ia.—This is an ideal treatment, I should judge, but in practicing in a mixed district, country as well as city, the injection treatment would be impracticable in a large number of cases. With inunctions, protoiodid or bichlorid internally, the disease does not yield as readily as by injections. So in city practice, in properly selected cases or in rebellious cases I should judge the injection treatment would be desirable.

Dr. H G Anthony, Chicago—I never employ hypodermic medication as a routine method of treatment. It should only be employed in exceptional cases which will not yield to other methods of treatment or else in conditions which are dangerous to life. Under other circumstances it is my opinion that other methods should be employed. Ever since hypodermic medication has been used the profession has been endeavoring to find some new compound of mercury which was superior to any other Whether the one the Doctor advocates *to day is better* than those which have preceded we can only determine by actual experience, *but we do know that of all the compounds* of mercury used up to the present time none is so powerful as calomel, and therefore in severe symptoms of syphilis it is best of all to use It should be used in only a few doses, if two or three doses do not have the effect there is no use in carrying the method farther.

As to the technic, the Doctor plunges his needle perpendicularly to the skin It has been shown by Moller that with hypodermics of any oil thrown into the gluteal region of the cadaver and carried deeply one injection out of three enters a vein, and that is where there is danger from embolism. In their efforts to avoid an abscess they invented the method of carrying the mercury deep into the tissues, and in doing that the point of the syringe enters the vein and produces an embolus We can never tell when we will strike a case in which there is an idiosyncrasy to these poisons, where there will be intoxication This is seen in various cases, where it was necessary to incise the injection and curette the part to remove the mercury and its poisonous effects Should that become necessary it would be better to have the mercury deposited subcutaneously, and that can be readily done by using a long needle and depositing the mercury at least two inches from the entrance of the point of the needle. That is as good as carrying the mercury deeply

Dr Joseph Zeisler, Chicago—I do not feel like allowing this subject to pass without saying a word or two regarding *the undue* authoritative attitude which the reader of the paper assumes when he says he has used this method to the exclusion of all others, and hopes we will *adopt the method* The fact is, there is absolutely no method of treating syphilis on record which will surely promise the avoidance of a relapse, and that would be the only criterion, in my opinion. for a method we should be willing to adopt. We use mercury to day for the treatment of syphilis, unfortunately, I would say, because I am not in love with mercury as a remedy, I look on it as a very poisonous substance which we use for want of anything better. We use it in a symptomatic way; all we can accomplish is the removal of symptoms If Dr Heidingsfeld will undertake to treat a patient with hypodermic injections of this gray oil for years I admire his tenacity and the nerve of his patient Besides, we know that we can not surely cure syphilis with any one method, and it will not do to say one method is better than others; we know that many physicians treat syphilis successfully with internal administration of mercury *only, or with injections* of the bichlorid, or inunctions, which are not to be forgotten, and we have no right to put one method before another, the selection of this or that method is a matter of personal like and dislike.

I want to call attention to some defects in the Doctor's technic. In using mercurial injections I would never employ a *metallic* syringe. Mine are made of hard rubber, except the needle, which must be of steel. My needles are twice as long as these. I do not think the Doctor should urge his instrument and technic too strongly on those acquainted with the injection treatment of syphilis.

Dr. Ludwig Weiss, New York—As regards the choice between ointment or subcutaneous treatment of syphilis, I maintain that inunction is the dirtiest but the best method, and the fact that it is somewhat unclean ought not to deter us from using it. Whether or not absorption takes place by pressing the mercury *globules into the skin—globules* of mercury have been found in the follicles—is a moot question. I always use inunctions unless compelled, by other *indications* which forbid their use, to employ some other method. It is true that the injection method is clean; it is true *that we can* gauge our dosage and make it much surer, at the same time we store up mercury *in the system the action* of which sometimes we are not able to stop. It happened to me in one case, where *the patient* had a most vigorous elimination of mercury through the salivary glands, as much as three pints a day. The patient died later of brain syphilis and exhaustion If the patient had been on the injection treatment the stored up mercury would have increased and made uncontrollable this terrible salivation He was taking inunctions, however, and I stopped the treatment immediately, and so could stop the salivation. There is an advantage in using inunctions, inasmuch as you can stop the treatment and absorption of mercury In conclusion I will say *that* by the use of soluble mercurial preparations, like the bichlorid, we need not be afraid of embolism. I would always prefer to use the inunction method, but in using the injection method would recommend the soluble preparations.

Dr M. L Heidingsfeld, Cincinnati—Most of the objections which have been raised in this discussion, in regard to this method of treatment, have been carefully considered and, I believe, fully answered in *the body of the paper.* I have studiously avoided giving this preparation the preference over any other preparation of mercury, or this form of treatment over any other form of treatment, except on purely empirical grounds, clearly evident to any casual student of medicine. Whether *these preferences hold or not must be* determined, not by blind skepticism, but also by empiricism, gained from clinical experience. So many preparations and methods of treatment have already been tried and found wanting that a certain amount of skepticism relative to every new form of treatment is readily pardonable, and our preference is naturally for that form which has served us best. If the injection treatment has served best in rebellious and exceptional cases, it seems to me that there can be no valid reason for not using it in every case, unless it be that it distresses sorely or is poorly tolerated If it is mercury, and *mercury only,* which *is the effective agent in the treatment* of syphilis, I can not concur with Dr. Anthony that its salt, calomel, is more powerful, unless it can be proven that it is more easily assimilated, or can be administered in relatively larger dosage. The danger of embolism is, I believe, as I have endeavored to show in the paper, a very much overrated proposition. Moller's investigations and Lesser's views have been disparagingly criticised, notably by Harttung.* My personal experience of over 3,000 injections, without a single *well-defined instance, speaks for itself. Dr. Ziesler's* objections to the use of a glass metallic syringe are apparently not well sustained. There is but little metallic substance that is not protected by glass or the leather washers in the syringe for the mercury to attack. The most exposed area is the necessarily metallic needles, and if the Doctor is consistent he should not use injections at all. The greatest harm which could result from this action would be the gradual erosion of the syringe; the preparation, I believe, does *not materially suffer.*

In the preparation and presentation of this paper I have endeavored to carefully observe a conscientious conservatism in all its details, and I trust to the clinical empiricism of the future as to whether conservatism or fervent enthusiasm were the dominating features

Rapid Transit Vibratory Massage.—The *New York Medical Journal* has found a bright side to the terrible jolting on the rough tracks for our municipal street railway systems. It recommends traveling for the purpose of securing the involuntary vibratory gymnastics, which are a fad in some quarters.

REPORT OF A CASE OF FIBROMA MOLLUSCUM.*

HENRY G. ANTHONY, M.D.
PROFESSOR OF SKIN AND VENEREAL DISEASES, CHICAGO POLICLINIC.
CHICAGO.

NARRATION OF CASE.

The patient to whom I wish to direct your attention is a young lady, 25 years old, whose parents are living and healthy. She has several brothers and one sister, who are also in perfect health. No member of her family has had skin lesions similar to hers. There is no family predisposition to tuberculosis, carcinoma, malformations, developmental defects, nevi or insanity. Syphilis may be excluded. Her parents are well-to-do. She has always enjoyed the comforts of a good home, and has never been exposed to the inclemencies of weather. She has never done hard work. Her time has been spent in school and in travel. She has never had a severe illness, excepting spinal curvature, which necessitated the use of a spinal brace from the age of 10 to 16 years. She menstruated when 16 years of age and has been regular.

Present Condition.—The patient consulted me because of seborrhea of the scalp, which has recently caused considerable loss of hair, and also because of an eruption of the skin which has been present ten years. The eruption does not produce itching or other subjective symptoms; it is annoying simply because of its cosmetic effect. It does not appear in crops; it is a steady, continuous development, constantly increasing, never disappearing, but the increase is very gradual. It is imperceptible from month to month. It can only be noticed by comparing her present condition with her condition as it was several years ago.

On examination we find that there are two kinds of lesions present: spots of pigmentation and tumors.

Pigmentation.—The spots of pigmentation are lentigo-like, of a yellowish color, some being of such a light shade of color as to be scarcely perceptible, while others are like freckles, or the pigmentation of senile atrophy of the skin. The disease began ten years ago with the appearance of these pigmentary lesions. They are found scattered here and there over the chest, abdomen, back, arms, upper part of the forearms, thighs and upper part of the legs. They do not coalesce or follow the course of nerves. They occur sometimes in groups of six to ten, and sometimes they show no tendency to grouping. The individual spots are oval or rectangular in form. They are from pinhead to split-pea size, and somewhat larger. They are somewhat darker in the center than on the periphery.

The skin of the feet and lower part of the legs, the hands and lower part of the forearms is normal. The neck is thickly set with split-pea size pigmentations of a bronze color. The skin of the face is of a light bronze color, which, fortunately, is not mottled, hence it is not very noticeable.

The patient and the members of her family are very positive that this pigmentation of the face has been present since birth, and that only the freckle-like lesions are a later development. They believe that the skin of the face is of a darker hue simply because the patient is a brunette.

That it differs from the normal skin may be shown by the contrast of color when the back of the hand is placed near the cheek.

The Tumors.—These lesions commenced to appear seven years ago, and three years after spots of pigmentation were first discovered. They begin as flat plates of induration, of a doughy or pasty consistency, situated in the derma. They are oval or rectangular in form, with a long diameter of from one-half to one centimeter. The color of the integument covering the plates is sometimes normal, in which case they can best be detected by palpation. Sometimes it is of a pinkish or rosy hue. Sometimes the skin is slightly elevated, and sometimes there is no elevation. Sometimes plates develop beneath a spot of pigmentation, and again they do not.

Later, the central portion of the plates softens and becomes slightly elevated, presenting a pseudo-vesicular lesion surmounting the disk. In still older lesions this central softening increases, the pseudo-vesicular lesion becomes elevated one-half to one centimeter, and even more, forming a gelatinous teat-like tumor, the apex of which presents an opaque, mother-of-pearl appearance, resembling collodion or the umbilical cord, while the base of the tumors is covered with normal integument. Some appear as if they were about to rupture, a method of involution which has never been observed, nor have any of them disappeared, leaving scars.

The largest of these tumors (Fig. 2) is situated in the popliteal space of the left leg. It is the size of a hazelnut. One is quite convinced that, if incised, a jelly-like contents may be squeezed out, but such is not the case. They simply bleed profusely. There are about 100 of these tumors scattered irregularly over the entire body. A few are beginning to appear on the face; on the extremities they are situated mostly on the flexor aspect. There is one on one foot and another on a finger.

By placing a finger on one of these nipple-like tumors it may easily be pressed downward into the skin, conveying a sensation as if the integument is pierced by a hole; the wall of this hole is firm and formed by the peripheral portion of the tumor, which has not yet undergone softening. This peculiarity was also observed in Taylor's case. When released, the tumor springs back to its normal position.

On the back are three sessile fibroma molluscum, and one plaque of pigmentation larger than the lentigines. It is about two inches long and one inch wide. There is another similar plaque on one thigh. (See Fig. 2.)

On the anterior surface of the chest there are two or three punctate, bright red, elevated, telangiectases, angioma simplex of Virchow, angioma senilis of Dubreuihl.

The mental condition of the patient is normal. The mucous membrane of the mouth is normal. The finger nails and toe nails and hair are normal. The urine is normal. All visceral organs are normal. The pulse and temperature are normal. The thyroid gland is not enlarged, and there are no enlarged lymphatic glands. None of the stigmata of hereditary syphilis are present. There are no tumors about the eyes, and no pterygium.

POSSIBILITIES OF DIAGNOSIS.

We must consider the possibility of this being two distinct and separate diseases in the individual, one of which is a pigmentary disease and the other multiple tumors, and we must also study the case with the possibility in view that this is a single disease, producing both pigmentation and tumors.

Xeroderma pigmentosum requires no serious consideration where there are present lentigo-like pigmentations of long standing, without telangiectasis, atrophy and epitheliomata.

Lipomatosis subepidermalis universalis of Kromeyer,[1] might be considered in connection with the tumors alone.

Kromeyer, you will remember, observed a girl of 10 years of age, who, since infancy, had had lesions on the body, which the mother called blisters. The lesions looked like the bullæ of pemphigus, but were firmer. After incision, fat tissue was squeezed out and microscopical examination of excised tissue showed that the lesions were fatty tumors, situated in the derma.

In Kromeyer's case there was a greater resemblance to bullæ than in my case, and pigmentation was not present.

Inasmuch as Osler[2] has stated that pigmentation of the skin is a common event in splenic anemia, and as there is one case on record of fibroma molluscum in which splenic anemia came into consideration, the case of Webster,[3] the clinician should carefully consider this possibility of diagnosis in all cases where the pigmenta-

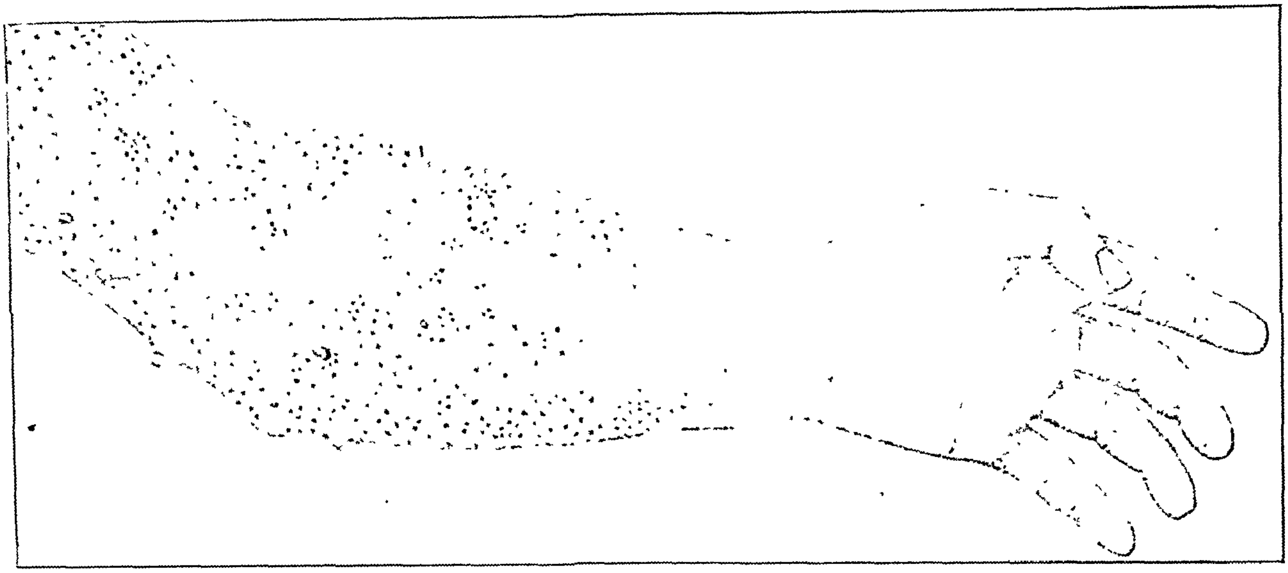

Fig. 1.—The lesions on the arm.

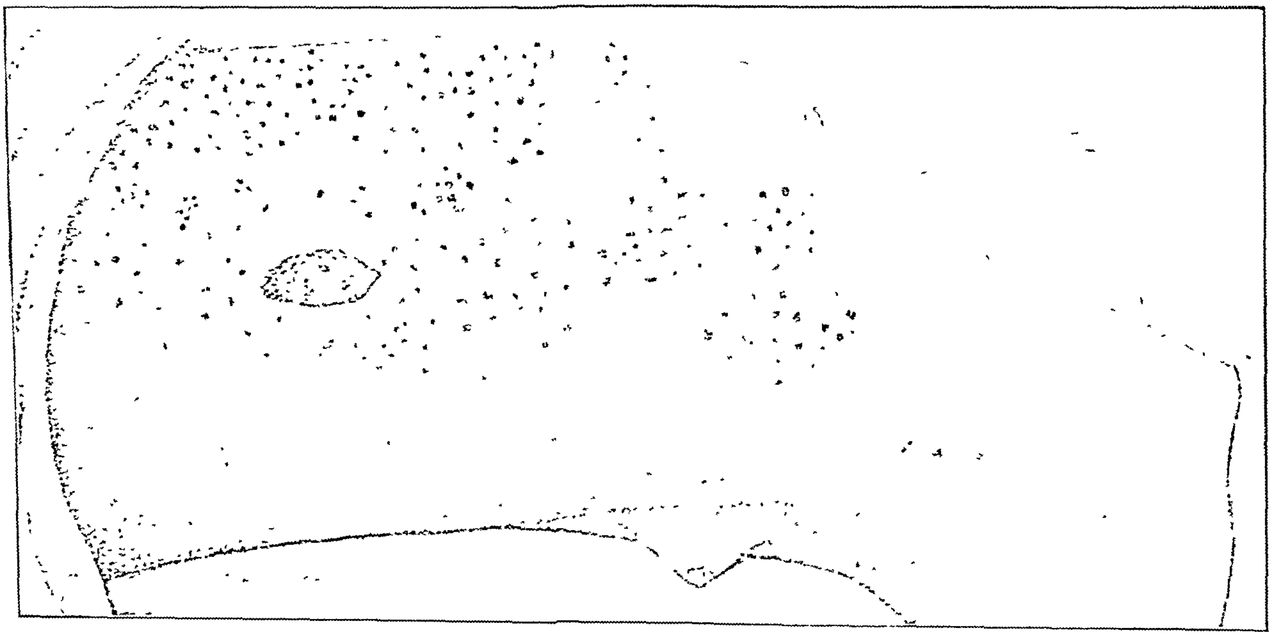

Fig. 2.—The lesions on the leg.

tion is accompanied by enlarged spleen and chronic anemia.

Osler describes the pigmentation of this form of anemia as being of a steel-gray color, like in argyria, and he states that it is possibly produced by arsenic.

Arsenical melanoderma could be excluded in my case, because of the fact that part of the pigmentation, that of the face, was present at birth and also because of the fact that the patient took no medicine before the freckle-like eruption appeared, when the patient was 15 year-old.

Colloid degeneration of the skin differs from our case in the fact that the tumors in that disease are waxy and not so large, so soft or so disseminate, and pigmentation is not present.

Addison's disease should be carefully considered as a possibility of diagnosis, as there are several cases on record in which cutaneous tumors were present, and also because it is possible that the statement of the patient and her family that the bronze pigmentation of the face was present at birth might be incorrect, and there are a few cases on record of freckle-like pigmentation occurring in Addison's disease.

The patient had what was diagnosed as curvature of the spine in youth. Why is it not possible that this was tuberculosis of the spinal column, or Potts' disease, and that we now have tuberculosis of the suprarenals? Examination of the spine shows no deformity or thickening of the bone. The disease has lasted ten years, and there are only two cases of Addison's disease on record which lasted that length of time.

Levin[1] says that the mucous membrane of the mouth is pigmented in 22 per cent. of the cases of Addison's disease. Those parts of the body in which we would especially expect to find pigmentation, such as the axillary region and nipples, are not especially involved.

Fibroma molluscum is the only other diagnosis which requires serious consideration, and it is also the only diagnosis which is sufficient to explain both the pigmentation and the tumors.

Pigmentation has frequently been observed in this disease. The tumors which we have described are not the ordinary pedunculated and sessile tumors of fibroma molluscum, but they resemble in many particulars the tumors present in Taylor's case.[5]

Microscopic examination confirms this clinical diagnosis. A spot of pigmentation and also pseudo-vesicular tumor were removed from the arm with a cutaneous punch. The specimens were hardened in Zenker's fluid, passed through Gram's solution, successive strengths of alcohol, imbedded in celloidin, and the sections stained by various methods.

The Pigmentary Lesion.—The stratum corneum is thickened, especially around the follicles. This thickening is not due to an increase in the number of layers of the horny layer of the skin, but to the fact that the individual cells of this layer are less compressed than normal. They are more hexagonal in form than in any other case of fibroma molluscum I have examined. This peculiarity of the stratum corneum is present in all parts of the pigmentary specimen, and also in the tumor specimen. Sections taken from the peripheral portion of the pigmentary lesion show the pigment irregularly scattered through the rete Malpighii, being present in abundance in some parts of a section and almost absent in other parts. It is located especially in the deeper layers of the rete and, in general, resembles the pigmentation of the negro. In the peripheral sections we note some tendency to the downward prolongation and dumb-bell shape of the rete pegs mentioned by Unna in describing pigmentary nevi, certain sarcomas and xeroderma pigmentosum.

On cutting the central portion of the pigmentary lesion, we are surprised to discover a microscopical-sized molluscum, the presence of which we did not clinically suspect. It is located around a sebaceous gland. It does not differ in structure from the tumor present in our tumor specimen. The epidermis over it shows far less pigment than sections taken from the periphery of the specimen.

The Tumor.—The mucous layer, especially over the central portion of the tumor, shows pressure atrophy.

Stained with polychrome methylene blue or by Van Gieson's method and examined with the lower power of the microscope, the tumor mass appears to be composed of a gelatinous or colloid mass, showing some fibrous structure in the peripheral portion of the tumor, but absolutely structureless in the central portion, until the diaphragm of the microscope is closed, when it may be seen that it is nowhere devoid of structure.

The gelatinous mass is thickly studded with strongly refracting nuclei of connective tissue cells. Mast cells are not present in this tumor. We have observed them in some cases of fibroma molluscum, always located on the border of the central gelatinous mass. We can not concur in the opinion of Unna that fibroma molluscum is made up of misplaced epithelium cells. It is my opinion that the entire tumor is composed of a myxofibrous connective tissue of embryonic type, the individual cells of which are occasionally round, but usually are spindle-shaped or else show various modifications of the spindle-shape, and that the nuclei which show such great power of refraction are the nuclei of these spindle-shaped embryonic connective tissue cells.

It is extremely difficult to obtain good preparations of the individual cell. The technic which proved most satisfactory in my hands is the following: A thin section is stained with hematoxylin and eosin. The collodion is dissolved out of it. It is shaken in a test tube for one-half hour. This tears the specimen. A minute fragment of the specimen is selected, teased with needles, and mounted in glycerin, or the specimen may be stained with polychrome methylene blue, in which case I decolorize in wood alcohol rather than in 33 per cent. tannic acid, which is employed by Unna.

I agree with those authorities who believe that fibroma molluscum is a developmental defect. Their point of origin has been the subject of much discussion since von Recklinghausen advanced the theory that they develop from nerve sheaths. I concur in the opinion of Crocker, who says that they may originate anywhere in the derma or subdermal tissue.

For some unassignable cause, the embryonic connective tissue cells which are spindle-shaped and have elongated nuclei, retain these characteristics in certain locations, and in extrauterine life these deposits of embryonic connective tissue develop, forming the tumors which we clinically call fibroma molluscum.

Being a developmental defect, we are not surprised that fibroma molluscum should exist in families, though this is by no means as common as some writers would have us believe, nor are we surprised that it should sometimes be accompanied by other developmental defects, such as asymmetrical development of the face, as in the case of Danlos,[6] or generalized ichthyosis, enlarged thyroid and nervousness, possibly Basedow's disease, as in the case of Hallopeau,[7] or fibroid tumors of visceral organs, or mental defect, as in a number of cases, or that accompanying the general pigmentation, the skin of the neck should present the appearance of xeroderma pigmentosum, as in the case of Brigidi,[8] or that there should be present patches, one-half of which were telangiectases and the other half pigmentation, as in Crocker's case.

I believe that telangiectases occur in association with fibroma molluscum far more frequently than is generally believed.

CENTRAL SOFTENING OF FIBROMA MOLLUSCUM.

The point of greatest interest in connection with the tumors of this case is the central softening which was present in the older tumors. Reasoning *a priori*, one would suppose that the central softening was due to degeneration analogous to that which may be observed in uterine fibroids; such is, however, not the case. I can find no difference in the histologic structure of those tumors which clinically show central softening from those which do not show central softening.

I believe central softening is due to location and the manner of growth. Where the tumor is superficially located and tends to spread laterally, as it increases in size, central softening will occur, while where situated more deeply and showing less tendency to lateral development, it will assume the ordinary forms of sessile and pedunculated or subcutaneous fibroma molluscum.

THE PIGMENTATIONS OF FIBROMA MOLLUSCUM.

In my opinion, pigmentation is just as much a part of fibroma molluscum as is tumor formation.

Stelwagon[9] is almost the only author of a text-book who describes these pigmentations. He says: "Other lesions sometimes associated are brownish pigmented stains, sometimes freckle-like, small or large areas, and *occasionally more or less defined discolorations.* While, as Wickham states, some authors touch on this feature, present in many cases, by others it is entirely ignored. In Wickham's eight generalized cases such pigmentary conditions were present in all."

Brocq[10] says that these pigmentations are nevi and that they are usually present in association with the tumors of fibroma molluscum.

Besnier[11] says the tumors are nevi, but makes no mention of the pigmentations.

There have been a good many cases reported in which pigmentations were present.

The pigmentations are of two kinds—large plaques and lentigines. The large plaques are the more common They have a distinct outline. They are dollar to hand size, and even larger, and present various shades of yellow and brown color. Sometimes there is but a single patch present, and sometimes the patches are quite numerous The back is their favorite seat of location

Why abnormal pigmentation should be present in some cases of fibroma molluscum and not in others is not known.

The histology of pigmentations occurring in association with developmental defects has not been sufficiently studied. Even in the latest reported cases of xeroderma pigmentosum and fibroma molluscum, the microscopic findings of the pigmented areas are not recorded

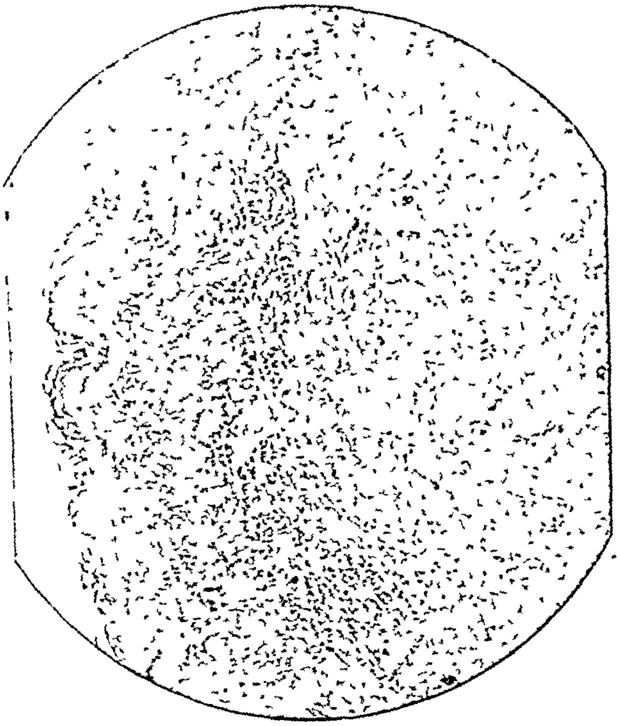

Fig 3 —Tissue under low power of microscope

Duhring[12] says "While, in the white race, pigmentation of the skin is due mainly to the deposit of pigmentation in the mucous layer, the connective tissue of the corium probably plays the principal part in its production This observation is particularly noticeable in pathologic conditions."

Fibroma molluscum, as is well known, is a common malformation in the colored race I have observed the large plaque variety of pigmentation on the backs of negroes on several occasions They stand out prominently from the general pigmented surface, because of a different shade of color. The freckle-like form I have only seen in the white race, it is rare, and when present is usually associated with large plaques and is apt to have an extensive distribution

Severe and wasting diseases sometimes precipitate the development of both the tumors and the pigmentations, in fact, patients often state that the first evidence of disease was observed after an illness. Careful questioning, however, usually elicits the fact that there were some lesions present since infancy.

I am convinced that some cases of this character have been reported as cases of Addison's disease associated with tumors, and where no disease of the suprarenal capsules was found on postmortem, arsenic has usually been assigned as the cause of the pigmentation. That there could possibly be any relationship between the pigmentation and the tumors is not mentioned in the report of any one of these cases. When once observed, the diagnosis of the pigmentation of fibroma molluscum is not a matter of difficulty Had my case been seen in infancy, at which time there were no lesions present excepting a light bronze color of the face, contrasting with the color of the general integument, we undertake to say that there are but few clinicians who would have diagnosed beginning fibroma molluscum, and yet this diffuse light pigmentation of the face is, in my opinion, one of the characteristics of this condition, worthy of especial attention, as I have seen it in other cases.

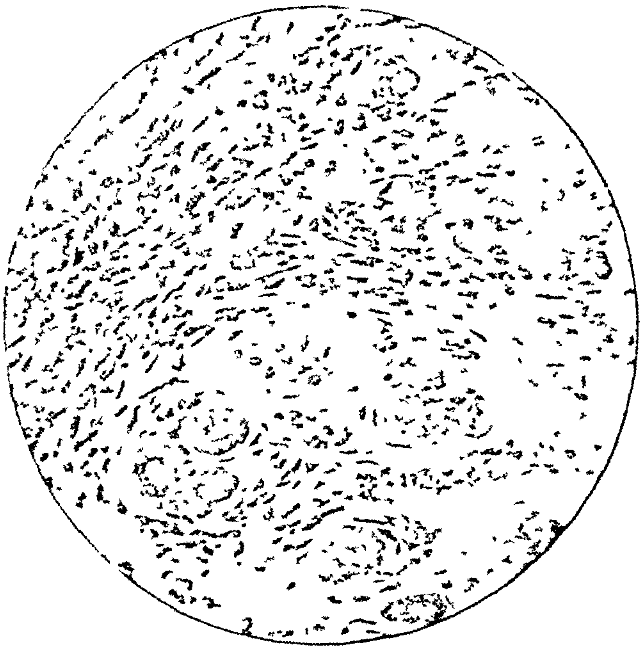

Fig 4 —Same High power.

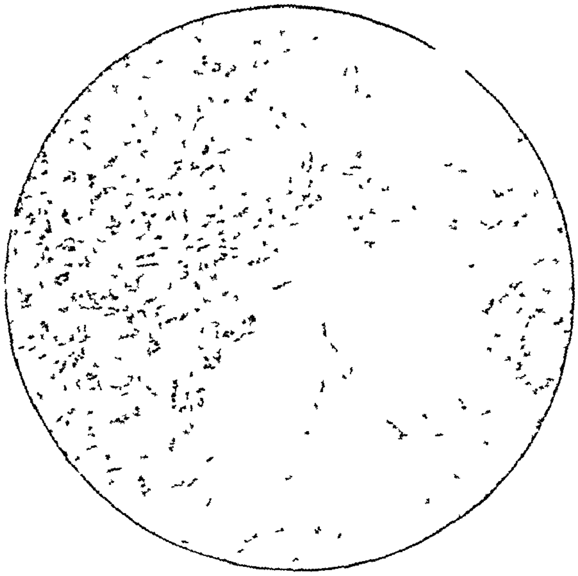

Fig 5 —Teased specimen of tissue

Cases may be observed in which tumors are present without pigmentations. Cases may be observed in which both tumors and pigmentations are present, and I believe cases may be observed in which pigmentations are present without tumors.

A few years ago I observed a lady who presented a peculiar pigmentation of the face. It was diffuse, of a light yellow shade of color, very noticeable, limited to the face and neck. I learned that she had always had this color and that her sister was afflicted in the same way. I examined both of these women, but found no evidence of fibroma molluscum in either of them; nevertheless, that was the only diagnosis I could offer.

Crocker[13] says: "Sangster showed a young man to the Dermatological Society, in 1893, who had extensive freckles and pigment patches of a square inch in size all over the body, buttocks and thighs, nearly to the knees. The face was free. It began in the first or second year of [illegible]. A brother had the same, and his mother, who [illegible] cancer, was similarly pigmented on the upper [illegible] the chest."

With [illegible] history and typical pigmentations, I would [illegible] to make the diagnosis fibroma molluscum [illegible] formation.

DISCUSSION.

DR. M. L. HEIDINGSFELD, Cincinnati—Dr. Anthony's instructive paper appeals to my particular interest, because I have had occasion to report some clinical data and the results of a pathologic study of a typical case in the *American Journal of Dermatology*, July, 1900. This case also showed, in addition to hundreds of large and small sessile and pedunculated excrescences, a large number of pigmentations which closely resembled ordinary lentigines. Small areas of leucoderma were also in evidence. I endeavored to determine in the pathologic investigation the exact nature and the origin of these peculiar growths, whether or not they were derived from pre-existing connective tissue (Rokitansky) fat, (Virchow) or hair follicles (Fagge). No special technic was employed in order to attempt to confirm von Recklinghausen's opinion that they are neurofibromata and are derived from medullated nerve fibers. My efforts were particularly directed to determine whether or not these forms of growth could be distinctly classed with the fibromata or connective tissue tumors. Connective tissue reduplication in the form of tumor formation is one of the rarest conditions encountered in dermatology, which is remarkable when we consider with what frequency and facility the other elements of the skin, glands, epidermis, fat, etc., reduplicate themselves. There is only one distinct form which can be readily classed with the true fibroconnective tissue tumors, and that is true keloid. False keloid, because it shows no tendency to enlarge or progress beyond a certain point, can scarcely be classed with the fibroconnective tissue tumors. The cells of the molluscum fibromata contained irregularly or oval-shaped nuclei, uniformly distributed in an almost homogeneous intracellular substance, which is faintly fibrillated, but the fibrils can not be traced to any distance, as in the case of the ordinary forms of fibroconnective tissue, and even embryonic connective tissue. Although the cells are somewhat spindle-shaped, there is no marked progressive change towards elongated connective tissue-like spindles, and nowhere is there any evidence of a distinct connective tissue formation, which is an important link, when we try to class these growths with the embryonic connective tissue group. There are many minor distinguishing features which also serve to distinguish these growths from each other and place them in separate classes. In other respects my findings conform to those of Dr. Anthony. Hair follicles were present, but showed no cystic dilatation and no hypertrophy, but rather pressure atrophy. Mast cells were abundantly present, particularly at the periphery of the growth in the surrounding connective tissue.

DR. L. DUNCAN BULKLEY, New York—In regard to therapeutic measures in these cases of molluscum, we know nothing to do for them as a rule but excision. I have a man under my care who must have had many thousands of these little tumors. I have been using on some of these little tumors a high-frequency electric current with a carbon electrode. The effect of this is to inflame them and cause a superficial slough; under this many of them have shrunken down and are disappearing. As far as I know this is a new method of treating multiple fibroma. In the three or four weeks I have been applying this method many of the tumors have shrunken and disappeared. I merely suggest it, but would like to have those who have static machines try it.

DR. JOHN A. FORDYCE, New York—I find among the photographs which I brought to the meeting one which is almost a counterpart of Dr. Anthony's. I have seen two cases of molluscum fibrosum with pigmentation of the skin of the type he describes. Minor grades of pigmentation in connection with the affection are not so uncommon. The development of the two conditions are probably closely related.

DR. HENRY G. ANTHONY, Chicago—In answer to Dr. Heidingsfeld, I excluded xeroderma pigmentosum. There is no leucoderma in this case; I did not mention it because I was not trying to embrace everything known regarding fibroma molluscum. The histology of fibroma molluscum has long been a subject of discussion and a great many men have worked along the line of trying to determine what relation it has to the nerves. They have not paid sufficient attention to the histologic structure of the cells. When I had separated the individual cells so that I could see them I concluded they were embryonic connective tissue cells; they resembled that more than anything else. I took my specimen to a general pathologist and asked, "Do you think those are embryonic connective tissues?" He said, "Certainly! where did you get them?" Then I consulted another man without telling him where I obtained the tissue, and asked him what it was. He said the same thing. The idea I have in mind is this: We know that the cells of the embryo are first round and then they become spindle-shaped with a marked nucleus, and under normal conditions these embryonic cells are transformed into connective tissue cells in the latter part of intrauterine life. For some reason, possibly the presence of the toxins of the chronic infectious diseases, this change does not properly proceed in certain locations, scattered here and there over the surface of the body. Then the individual is born with deposits of embryonic connective cells, the presence of which is not suspected until the system is subjected to a severe strain, such as puberty, as in my case; then these hidden deposits of embryonic connective tissue grow and produce the tumors which we call fibroma molluscum. Supposing the strain which caused these deposits of embryonic connective tissue to develop should be tuberculosis of the apex of the lung, when the diagnosis which has always been made up to this time has been tuberculosis of the lung, pigmentations of Addison's disease, from tuberculosis of the suprarenal capsule and "tumors which the dermatologist calls fibroma molluscum." In other words, the clinician does not realize that there is a relationship between the tumors and the pigmentation. As I have shown, any pathologic condition of the derma may cause a hypertrophy of pigment in the epidermis, hence were concealed deposits of embryonic connective tissue cells present in the derma they could easily produce a case in which pigmentation would be present without tumor formation.

The case Dr. Fordyce shows closely resembles mine and the fact that pigmentation was also present in his case should convince every one that I am right in stating that it is an essential part of fibroma molluscum.

THE TREATMENT OF LEPROSY.

DISCUSSION ON THE PAPER READ AT NEW ORLEANS BY A. H. OHMANN-DUMESNIL, ST. LOUIS.*

Dr. Jay F. Schamberg, Philadelphia—Some of those present will doubtless remember the reports published by Dr. Dyer a few years ago on the results of antivenomous serum in the treatment of leprosy. I had occasion, three or four years ago, to use in the Municipal Hospital of Philadelphia some antivenene, obtained from Dr. Calmette of Lille, France. The leprous patient received 9 injections of this serum, each injection being followed by a febrile reaction. At the end of the ninth injection the temperature rose to a considerable degree and the patient passed through a long febrile course which was recognized as a typical typhoid fever, which disease was prevailing to an alarming extent in Philadelphia at the time. The development of typhoid fever was, of course, a pure coincidence. The leprous manifestations were not influenced by the serum nor by the typhoid fever, and the fever itself was not in any way modified by the chronic infectious disease from which the patient was suffering.

Dr. J. H. Duncan, St. Louis—We do not see much of leprosy in St. Louis. About two years ago I had a patient living in one of the Gulf cities. I exhibited the case to our Willan Dermatological Society. Examination was made of sections from the nodules by Dr. Engman, and it was pronounced leprosy. One case of leprosy from St. Louis had been to Unna and returned after two or three years apparently cured; there were no lesions and the patient seemed well, as our cases of syphilis seem well. I was not prepared to treat leprosy, and at the suggestion of Dr. Engman I referred this lady to Unna, and she went. That is over two years ago, and she has written me probably three letters, each letter stating that she is improving, the disease is disappearing, but the Doctor tells her she must stay a year or two longer. A few months ago her brother came to me with letters and pictures from her, photographs of the condition of parts of the body taken when she went to Unna and of the same parts taken eighteen months after she went there, and the change in the appearance of the part to me, who am not very familiar with leprosy, was most marked. She wrote most glowing letters about the disappearance of the lesions.

Dr Dumesnil speaks of a cure. I do not know what he means, but the case which came back from Unna three years ago is to all appearances well. I am told he still takes internal medicine.

Dr. M. P. Vanderhoeck, Minneapolis—I have had some experience with leprosy in Minneapolis. We have in Minnesota on record some 78 or 79 cases, mostly among Norwegians. In the treatment of those under my care I use local applications of chrysarobin, and I have seen nodules disappear in a day or two by being covered with chrysarobin paste. We have gotten good results from chaulmoogra oil; it always improves them. I had one patient who had lost one eye and had ulcers all over the body, the nodules being very pronounced. At the time he came under my care he weighed 120 pounds; he was taken to the City Hospital and isolated. We put him on chaulmoogra oil, with good food and hygiene, and later on he weighed from 190 to 200 pounds, and kept in good health ten years, until he died from an attack of pneumonia. None of these cases has been cured; relapses would come after the medicine was stopped, and sometimes the symptoms were graver than before. We have no ideal treatment for it; there is no cure we know of, but we all hope much from serum therapy. Our health officer has been watching the cases throughout the state, and with improved hygienic conditions is getting good results. The first case I mentioned came under my care in the fall of 1888, and I had him under close observation for ten years. He died in good condition so far as the leprosy was concerned. Others have died from tuberculosis.

Dr. J. N. Roussel, New Orleans—I would like to report a case in a man treated with chlorate of potash. The man was 50 years old. He had had the disease two or three years. The foreleg and feet were very much tumefied from about the middle third of the foreleg, with many ulcers present. The hands were also badly involved with tubercles and ulcers. The disease was of the tubercular type, and, strange to say, one side (the right side) was always worse than the other. He had lost the power of sensation entirely. I could apply the cautery to him without pain. After two months' use of the chlorate of potash the tumefaction began to disappear, sensation began to return, the ulcers all healed, and to-day, after about a year, he seems to be apparently well. He has no ulcerations, feels well, sensation is normal, and in every respect he is apparently well.

Dr. John A. Fordyce, New York—In the class of infectious granulomata to which leprosy belongs it is not unusual to see the tumors disappear by spontaneous involution. We see it in syphilis. I have had a good many lepers under observation in the hospital, and under better hygienic conditions and chaulmoogra oil the tumors disappear, but they usually come back again, while the patient's general condition grows worse. I have personal knowledge of one case in which a cure has resulted. This patient, a well-to-do woman, was under the care of Dr. Morrow of New York. She showed the pigmentary lesions of anesthetic leprosy. The Doctor informs me that he saw her within the last year and that all the skin lesions and the anesthesia had disappeared. She had had no recurrence after eight or ten years. That is the only case in which I have personal knowledge of a cure. I think in the anesthetic type the prognosis is much more favorable and a certain number of cases do get well, but they are usually badly deformed. In this particular case there seemed to be an absolute cure with little evidence of the disease having been present.

Dr. A. H. Ohmann-Dumesnil, in closing the discussion, said: Of course, we can all detail apparent cures. For instance, in the case of a woman from Mexico, a case of tuberculo-anesthetic leprosy, sensation was entirely gone all over the body. Under heavy doses of ichthyol internally, four grams three times a day, she had a well-pronounced ichthyolic fetor; in two weeks the tumors disappeared, and if I passed a fine hair over her neck she felt it. Unfortunately, she did not live long; in the St. Louis cyclone she fell dead of fright. I have been very unfortunate in not being able to follow cases for years. I have seen a cured (?) case of Unna's. In this pyrogallic acid was used for the tubercular lesions, and he gave her internal treatment with ichthyol. She improved some until she arrived in St. Louis, when she gradually got worse and worse and suddenly disappeared. So far as the cure is concerned, I found in these cases when I went deeply into the tissues I could find microbic changes indicative of the lepra process or the bacillus of Hansen. Until everything gives reactions and permits us to see that the tissues are all normal and the absence of specific bacteria is demonstrated, we can not say a case is cured. I am doubtful of the cure of a case of leprosy up to the present because we have had no opportunity of proving the matter definitely. Another thing, there is a question as to whether a supposed cure of leprosy is placed under conditions which will prevent a relapse. Is the patient so placed that there is no possibility of environment favoring a relapse? If the patient can be segregated for a number of years we can argue from that basis, but if other conditions are permitted to work, if there is the possibility of the original potential condition, it is difficult in order to secure proof of a cure to eliminate all the factors which may be potential in the development of the disease.

The Degenerate Thermometer.—Some physicians have been testing thermometers in common use in hospitals, and find them to vary in some cases as much as two and one-half degrees. In connection with the advertisements of cheap thermometers and of thermometers given as premiums, the warning is timely.

---

*The paper appeared in The Journal, May 16, 1903.

least twice daily during the first week after birth. In the presence of a temperature an artificial feeding of a modified cow's milk is indicated; it can do no harm even if there be another cause present for the rise, but it will generally be sufficient to cause a satisfactory and permanent reduction.

There may be an ample supply of a good milk, but the absence of a serviceable nipple may prevent the child's obtaining it. I have often seen this, and it is now my routine practice to make as early an examination of the breasts and nipples of a pregnant woman as possible, especially in primipara, in order to give instructions in the massage of flat and depressed nipples. By massage and training a very serviceable nipple can be made from an unpromising one if the treatment is begun early enough. The wearing of tight corsets or clothing should be advised against during pregnancy, but especially in the presence of flat or depressed nipples. A careful inquiry should also be made of multipara in regard to their lactation history, as having a bearing on the possibility of nursing the new baby.

An infant's progress may be watched by noting its weight, the presence or absence of vomiting, the stools, the time and amount of crying, but the most important, perhaps, all else being equal, is the weight. A newborn baby loses in weight during the first week, but by the end of the second week, or sooner, it should have regained its birth weight, and after this it should gain not less than four ounces a week.

A stationary weight or a loss after the second week; vomiting, not simply a slight regurgitation; colic; continuous crying; diarrhea, with green, mucous movements containing curds, should be an indication for a close investigation of the breast milk, the frequency and time of nursing and the daily routine of the baby's life.

I have had very satisfactory results from the employment of Holt's milk test for the clinical examination of breast milk, and have had good results in modifying breast milk to meet indications as shown by this test taken in connection with the symptoms presented by the child.

A high percentage of proteids is evidenced by colic, crying, with a doubling up of the legs, tense abdomen, green, mucous stools containing curds. This very often occurs while the mother is lying-in, but as soon as she gets up and is enabled to take the proper exercise, the increased proportion of proteids is generally decreased. Should this relatively high percentage of proteids with low percentage of fat persist, and the plentiful supply keep up, much help can be had from pumping or milking out the fore milk from the breast, the child being allowed to nurse only the middle milk and strippings. Taking the child from the breast before it has finished nursing and giving it a small quantity of barley water, previously dextrinized, from a bottle, will often relieve the colic, lessen the diarrhea and make the curds smaller.

Too much fat, which I have met but a few times, causes vomiting and diarrhea, with few or no curds in the movements. If too much fat is present there may be found in the stools small round masses which resemble curds very much, but are smooth and soft and not so white as curds.

A too small milk supply calls for active treatment. It is evidenced by a stationary weight or a loss in the weight of the infant; crying within a few minutes after leaving the breast and sucking vigorously on its fists after nursing. If the deficiency in supply is the only fault, it may frequently be increased by such galactogogues as nutrolactis or somatose, free drinking of milk, cocoa or chocolate and the cereal gruels. Alcoholic beverages are to be avoided, as they encourage the secretion of a milk with a deficiency in its life-giving properties and an increase in the watery element. If this does not correct the difficulty, the child should be put on a modified cow's milk, of suitable formula, in addition to the nursing, giving at first one or two drams to an infant of four weeks immediately after a breast feeding, gradually increasing the amount as indicated. This will generally suffice to obtain a satisfactory report as to its weight.

Holt's plan of having weekly reports sent on specially printed cards is to be commended. This report, which includes the babies' weight, stools, sleep, etc., enables him to watch the progress of those babies under his care and to put the proper interpretation on abnormal movements, restlessness or no gain or a loss in weight. In this way many babies could be saved perhaps serious attacks of bowel or digestive trouble by an early notification of abnormalities. Mothers are too prone to attribute digestive disturbances to teething, which, if promptly attended to, might prove of little moment; neglected, they might result seriously or fatally.

With a good milk supply, regularity of nursing, infrequent or no night nursing, a child will generally do well; a good supply with a disregard of these requisites will result, perhaps, in serious digestive derangements. Should a combined breast and artificial feeding be necessary, the one or two night feedings should be breast milk, if for no other reason than the convenience to the parents. The only objection to this is the possibility of the mother falling asleep and allowing the child to lie with the nipple in its mouth for several hours at a time.

A condition which may give rise to serious digestive disturbances is nursing from a cracked or fissured nipple. The milk is mixed with blood drawn from the crack, which results in an indigestion, vomiting, etc. Indeed, a fissured nipple may be so intractable as to prevent maternal nursing entirely.

We would advise against maternal nursing in a tuberculous mother, or one the subject of a serious puerperal infection. A suppurating mastitis is not a contraindication to nursing, as it is an exception for the abscess to invade a milk duct. Regular nursing is an assistance rather than a detriment.

The problems, then, to be met in the supervision of breast feeding would be: 1. The increase of a too small supply. 2. Changing the character of the milk, (*a*) decreasing the proteids, (*b*) increasing the fat, (*c*) decreasing the fat. 3. To make serviceable nipples out of flat and depressed ones. 4. To supply an artificial or adjuvant food in case of a good but too small supply from the breast. 5. To continue nursing during a suppurating mastitis and retain the integrity of the gland after a subsidence of the inflammation.

The every-day problems of an entire artificial feeding are even more difficult of solution than those of breast feeding. It is not possible to have a set rule for guidance in all cases. Cow's milk for most cases is unquestionably best, but we frequently meet with cases in which no formula nor any method of home modification can be made to agree with the child.

It is my opinion that none of the artificial foods are suited for long administration to an infant. Sooner or later cow's milk must be given in some form to prevent the nutritional disorders which are certain to follow their long and exclusive administration.

In the choice of artificial foods, and no one food or one dilution or combination will agree with every child, those should be selected with which it is possible to combine milk in some proportion. Condensed milk in combination with some of the milk foods or a small percentage of cream can frequently be borne when other foods or combinations have failed. Without some such combination the results from an exclusive condensed milk feeding will be far from satisfactory. Condensed milk has much to commend it, it is one of the best foods for the poor and ignorant, is generally within their means, is easily kept sterile and is easily prepared. Its chief advantage lies in the small percentage of fat when the milk is diluted according to directions sufficiently to bring the percentage of proteids within the limits of digestion. Its long continuance results in such nutritional disorders as scorbutus and rachitis, and when the necessity arises for giving another milk it is difficult to change because of the taste acquired for the over-sweet condensed milk.

If a cow's milk is to be used, and it should be tried whenever possible, it is necessary for the physician to master the problems of percentage feeding and adopt some method of calculation of the prescription. There are a number of these by which very satisfactory results can be obtained at home.

He should be perfectly familiar with the supply of milk, its analysis, place and mode of production and process of handling, modification at home, care afterward, care of bottles and vessels used in the modification.

Minute and careful written instructions should be given regarding the feeding of an infant, and these should not be diverged from at all. Like the treatment of typhoid fever in a child, eternal vigilance is the price of success. Trust nothing to nature unaided.

INFANT FEEDING.*

ALEXANDER McALISTER, M.D.

CAMDEN, N. J.

Both our common humanity and our public economy demand that all preventable infantile mortality be speedily prevented. That many deaths are preventable by the successful employment of known methods of feeding is clearly proven. According to a noted English statistician the present mortality among infants of his country is as high as it was fifty years ago. This is probably too gloomy an aspect to take of the subject to do justice to the facts in the case. That this statement does not apply to the American people may at least afford a measure of personal gratification, but the demands of a still too large infant mortality on our profession are none the less urgent and perennial. These demands are made on the entire profession rather than on the pediatric specialist, for, while the latter stands forth more and more conspicuously the leader in thought and action, it is on the rank and file of the army, the general practitioners, that the hardest fighting inevitably falls.

It has been observed that the general practitioner, regarded from the view point of his labors, is the great pediatric specialist of his day, yet that in point of his knowledge, as a rule, he fails to deserve that distinction.

In the selection of a subject the writer chose "Infant Feeding" because of its important bearing on infant mortality. It is not the purpose to cover the subject, or even to take up in detail one or more phases of this subject, but rather to dwell on a few of the most salient points of the present interest with reference to recent progress and changes in the artificial feeding of infants.

It is interesting to note the growth of sentiment against artificial feeding, except as a final resort. The importance of allowing infants at least part breast feeding whenever this is possible, is now being emphasized more than ever. We are waking up to the fact that there is much erroneous belief in regard to the inability of mothers to suckle their offspring. These are capital evidences of progress. The beneficent influences of proper feeding on the infant, child and adult are a well-spring of life, and conversely, the pernicious effects of improper feeding on the tender little being as long as life continues are a relentless and irremediable source of disease. Such being the case, how befitting that at each annual convention much time is devoted to the consideration of this subject.

Progress in infant feeding heretofore has been lamentably slow, at times almost inconceivable, yet none the less positive and commendable. Unfortunately we learn much simply to be unlearned again by tedious deductions and eliminations. The importance we attached to artificial foods twenty years ago and that attached to condensed milk ten years ago are familiar examples.

The failure to rate morbidity second only to mortality in the estimation of food values in the feeding of infants is fruitful of incalculable evils. The laity judges of food value by two time-honored standards, one being negative and the other positive. The first is that the infant does not die, or conversely, "that it lives"; and the second that the infant thrives, or as commonly stated, "that it grows fat." The latter is always based on very superficial observation, and forms the kernel of the higher valued testimonials which manufacturers utilize in exploiting the virtues of artificial foods.

How easy the task for medical men to commit the same errors of judgment, adipose tissue being peculiarly deceptive in artificially fed infants. The mere fact that the infant lives and is growing fat easily makes an increasing morbidity which fatally exposes the infant to the first attack of one of the acute maladies.

The writer is not one to lay the death of every infant to the charge of the food employed in its behalf. The method of feeding may be alone at fault. Both over-feeding and under-feeding have their train of pernicious results properly classed as food disorders. These are frequently more or less obscure and generally but vaguely definable. Sterilized or pasteurized cow's milk and the various artificial foods of the market are fruitful sources of such results of improper food and faulty methods of feeding.

On the other hand, it must be admitted that many an apparently thrifty infant's death is in reality attributable to deeply-rooted results of improper nutrition.

This strictly modern subject of morbidity is receiving increasing attention. We have come to the time when methods to reduce mortality and methods to reduce morbidity must be considered side by side and conjointly. The American Pediatric Society did a noble work simply in calling specific attention of the medical world to this important subject about four years ago in a general inquiry into the prevalency of scurvy and rickets in artificially fed infants.

The tendency of to-day is to return to Nature's beneficent provisions and methods and to have more regard for the specific needs of the individual infant. We have learned to recognize in cow's milk Nature's abundant substitute for mother's milk. We want simplicity in food and method of preparation rather than complexity and artificiality.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

We are ready to abandon wholesaling and turn our best attention to individualization. Wholesale sterilization or pasteurization is not much advocated in this, the twentieth century. Laboratory milk is not so much heard of now in the foreground of pediatric teachings. Sterilized or pasteurized milk is first class in specific instances and to meet special indications, but falls short of being the best at our command for all infants and all conditions.

The relative value of recognized methods of feeding infants as esteemed by leading pediatric specialists at home and abroad, in the writer's estimation, may be summed up in the following order:

1. Exclusive breast nursing.
2. Mixed feeding, the infant having the advantage of more or less breast milk daily whenever and so long as this is possible.
3. Cow's milk modified in the home, water, lime water or a simple demulcent being employed as a diluent.
4. Dispensary and commercially pasteurized milk.
5. Boiled top milk variously diluted to suit the infant's needs.
6. Whole cow's milk modified by admixture of one of the artificial foods.
7. Condensed milk and the several cereal and milk foods.

INFANT DIGESTIVE DISTURBANCES.*

A. C. COTTON, A.M., M.D.
CHICAGO.

Infancy and childhood are the periods of life in which digestive disorders are most prevalent and fatal. In children of all ages a transient form may occur at any season, with a decided predilection, however, for the heated term. In midwinter occasional attacks of more or less severe, although usually transient, diarrhea without fatal tendency are seen. It is in the three summer months that enteric disorders, with diarrhea as a common symptom, are most fatal. This clinical fact is so well recognized, indeed, that the term summer diarrhea has gained a prominent place in the nosology of early life.

The mortality among infants and children during the summer months from digestive disorders exceeds that from all other diseases during the same period. Comparative statistics show that the greatest susceptibility to summer diarrhea is found between the ages of 6 to 18 months, during which time the death rate from this cause is manifold that seen at any other age. The well-known mother's dread of the second summer is a clinical recognition of this fact.

The death rate seems to divide this subject into two classes, viz., early infancy and late infancy. It is a common clinical observation that the persistency of digestive disturbance, due to the introduction of an irritant, diminishes with the age of the child after two years. So that with increasing age there is a steady diminution in the severity of diarrheal disorders and a corresponding decrease in mortality from this cause.

The first class includes infants during the milk-feeding period up to about the middle of the second year, while the second includes infants from 18 to 36 months. After the latter age, severe attacks of diarrhea are so infrequent as rarely to require the attendance of a physician.

In these disorders the onset is sometimes sudden, ushered in by a convulsion, vomiting and diarrhea. There is usually high temperature, thirst and nausea which make the infant clutch at food, but push it quickly aside as soon as a few mouthfuls have been swallowed. Restlessness is nearly always present. The stools may change suddenly, or there may be an interval of two or three days of preceding departure from the normal in frequency and character. There may be a great deal of colicky pain.

The infant, while apparently in perfect health, may develop vomiting, the matter ejected being at first the contents of the stomach little changed, highly acid, or densely curdled, to be followed soon, however, by a watery mucoid and sometimes by bile-stained fluid, less acid or even alkaline in reaction. Diarrhea frequently accompanies and invariably follows the onset of the disturbance. The first dejections may be nearly normal, but quickly change, showing evidence of fermentation and later of putrefaction, finally becoming serous. The odor of the stool varies from the normal acid to intensely fecal and later to a sickening, musty smell. The infant, apparently well nourished and playful, quickly shows signs of systemic disturbance in fretful, peevish irritability and restlessness, with head rocking, anxious facies, persistent whining cry, pyrexia, dry mouth, softened, flabby tissues and atonic musculature. The depressed fontanelle, sunken, lusterless eyes, sharply defined temporals, drawn features, with the intense thirst give evidence of the great drain of fluids. The abdomen, at first tympanitic, may soon become flabby and depressed, and the extremities may be cold, although the rectal temperature shows from 103 to 106 degrees. Convulsions may usher in the attack, follow the initial vomiting by a few hours, appear only at the final stage or occasionally may not develop. Within twenty-four hours from the onset, and frequently earlier, the algid stage is reached, with pallor and cold superficies, although the internal temperature may be high. The restlessness changes to a sopor accompanied by hyperesthesia and irritability when disturbed, but rapidly subsides into semi-coma, with shallow breathing, collapsed veins, pulseless radials, half-closed, filmy eyes and terminates in death by convulsion or asthenia.

This picture presents symptoms of acute poisoning from the gastro-enteric tract, occurring in a state of apparent perfect health, with fatal termination in from 24 to 48 hours. Although the well-nourished infant is not exempt from this form of acute intoxication, it occurs with so much greater frequency among those who show evidence of malnutrition that the latter condition may well be considered a predisposing cause.

Fortunately, cholera infantum, as just presented, with its almost invariable fatal termination, is by no means common. As to its frequency, it is extremely interesting to note the varying opinions of the most competent observers. One eminent observer of wide experience in diseases of children, stated recently in a public address that he had seen only three cases of undoubted cholera infantum. Other writers of equal eminence speak of its occurrence as more common and claim occasional success for certain therapeutic measures adopted in certain cases. These widely different opinions as to the frequency and fatality of cholera infantum may be reconciled only on the ground that we have no common standard for the diagnosis of this grave disorder. The prevailing opinion seems to be that so-called cholera infantum is extremely rare and almost invariably fatal, and against which no therapeutic procedure has thus far proved efficient.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

So far as antemortem clinical evidence goes, cholera infantum may be considered an intense form of acute gastroenteritis or a dyspeptic diarrhea plus some unknown intoxication.

Clinically, the line can not be sharply drawn between some cases of dyspeptic diarrhea and cholera infantum. It is within every clinician's experience that occasional cases presenting all the symptoms of so-called cholera infantum, from the sudden onset of vomiting to the serous diarrhea, seem to yield to treatment and ultimately recover. Who shall say that these were not cases of cholera infantum? Is there not a tendency to restrict that diagnosis to fatal cases only? Symptomatically the differentiation between the various forms of "summer complaint" can not be made. That bacteriology promises an early solution to some of these questions is believed by many, and the attention of the profession is turned with renewed interest to the special work of Booker, Flexner, Duval, Bassett and others in their investigation along this line.

The commonest form of summer diarrhea is so evidently the result of acute indigestion that some writers have classified it separately as the dyspeptic variety. This classification seems justifiable when we recall the frequent history of the ingestion of substances known to be inimical to normal digestion. In many other cases which give no record of dietetic error we are led to conclude by analogy of onset, symptoms and progress that perverted or disturbed digestion from causes not apparent may be responsible for a large proportion of summer diarrheas. It is the common experience of every physician to meet cases of sudden onset of vomiting and diarrhea, with temperature varying from slight elevation to a high degree of pyrexia, with or without *history* of improper feeding in which relief with absolute recovery follows the exhibition of one or more doses of castor oil and the withdrawal of food for 24 hours.

The diagnosis of diarrhea due to acute indigestion seems in the majority of cases to meet all the pathologic and therapeutic requirements. Unfortunately, however, in many instances, the simple treatment outlined above is not applied, or if applied, fails to secure the desired results, and the case develops a most obstinate form of gastrointestinal disturbance. There is continuation of pyrexia, with colicky pains, more or less flatulence, frequent dejections of foul, acid, greenish stools of varying consistency. The vomiting may cease, but the diarrhea persists with increasing tenesmus, the stools becoming mucoid, bloody or serous, and either fetid or odorless. From the common onset the resultant disorder may be named according to the area apparently most involved, as gastroenteritis, enterocolitis, ileocolitis or colitis with or without proctitis. It is amply in evidence that obstinate enteritis with or without anatomic change in the mucosa of the gut, or even membranous or ulcerative colitis, may be the last expression of an acute attack of indigestion in the infant.

The systemic disturbance which seems to be an expression of intoxication from the stomach and bowels varies widely as the disorder locates with greater or less intensity on this or that portion of the digestive tract. The early cessation of vomiting is frequently accompanied by the subsidence of pyrexia, with improvement in the general muscular tone. Apparently systemic disturbance diminishes proportionately with the distance from the stomach at which the burden of the disorder seems to fall. Thus, in most obstinate cases of colitis with extensive lesions of the mucosa, nutrition is frequently maintained to a remarkable degree, the child showing but little evidence of systemic intoxication, whereas a much less obstinate disorder of the small intestine may cause prostration with symptoms of general infection. *In other words, the more* active the digestive area involved the more profound the constitutional disturbance and the greater the tendency to prostration and collapse.

Of the complications of summer diarrhea, the most common in young infants is stomatitis from simple catarrhal to the obstinate ulcerative variety. It becomes serious as it interferes with the ingestion of food and increases the restlessness and discomfort. Its persistency adds to the gravity of the prognosis. This complication is most often seen where the gastric disturbance is marked, and its improvement is usually in direct ratio with the improvement in stomach digestion.

Cough and rapid respiration, so frequently seen in acute or subacute gastroenteric disorders, is usually indicative of broncho-pneumonia, which may or may not yield marked physical signs. That it selects the most dependent portion of the lung adds to this infection the dangers of mechanical hypostasis.

The quite frequent occurrence of albuminuria in patients with summer diarrhea has led some observers to attribute the convulsions to uremia and the occasional so-called idiopathic edema to nephritis. The conclusions, however, are rarely confirmed by the postmortem findings. Functional cardiovascular conditions with the anemia rapidly induced by the colliquative discharges appear a rational explanation for many of the cerebral phenomena and the edemas of dependent parts.

*Lesions of the integument, from mere dryness or or*dinary intertrigo to the various forms of urticaria, furunculosis and local necrosis, are met with most frequently in the subacute and chronic diarrheal disorders. Whatever the local treatment applied they yield only to the improved nutrition of convalescence.

A prolonged digestive disturbance rarely leaves the infant free from evidences of retarded development, which in many instances is never fully compensated. The picture of a two-year-old set back to the plane of a yearling, both as to digestive and motor functions, is a familiar one, and the attempt to adapt his hygiene to age instead of to condition is a common error.

Perhaps the most important effect of severe summer complaint on the survivors is the feeble resistance to infection from lowered vitality, so that the danger from intercurrent diseases is manifold. The special hygiene for these little convalescents is a subject too frequently dismissed with the doctor at the conclusion of the enteric disorder.

It is safe to say that the fatalities of summer diarrheas are seen very rarely among the exclusively breastfed infants. They may starve to death from insufficient or impoverished breast milk, or dying from inherited dyscrasiæ they may show some of the symptoms of chronic indigestion. They may exhibit symptoms of acute or subacute digestive disturbance as a result of palpable errors in hygiene or they may be destroyed by some overwhelming intoxication, presumably due to sudden changes in the constitution of the breast milk, resultant from physical or mental disturbance in the nurse. In none of these instances is the symptom diarrhea essentially a summer diarrhea. Moreover, it is a common observation that the diarrheas of the exclusively breast-fed are usually tractable, regardless of season, in otherwise healthy infants, by the application of the well-known principles of hygiene.

The startling mortality from digestive disorders is confined almost entirely to bottle-fed babies. This fact is so generally established that when pronounced diarrheal symptoms appear in an infant at the breast the first interrogations are directed towards the possibility of the ingestion of other material than breast milk. A careful study of the infant's hygiene, with examination of the dejecta after colonic flushings, frequently disproves the statement that the child's diet included nothing but breast milk. Statistics show that in the fatal cases of summer diarrhea less than 3 per cent. were exclusively breast fed. No clinical phase of this subject begins to rival in importance this one fact, that summer diarrhea, with rare exceptions, means practically summer artificial feeding.

In view of our knowledge of summer diarrhea the question of feeding, then, is of paramount importance. A neglect to use every means to secure for the infant natural food can not be atoned for by the most energetic therapy yet devised. Many of the obstacles to natural feeding are insuperable or even formidable only so long as the lay mind is asleep to the fact that his physician knows how to prevent fatal digestive disorders in the infant. When the responsibility for the consignment of a baby to a method of feeding that diminishes his chances of living two-fold more than inoculation with smallpox virus is fully brought home to the physician the difficulties of breast feeding will become proportionately insignificant. The fact that some governments and municipalities now require on the infant's death certificate a statement as to the method of feeding shows an awakening to the importance of this matter. How long before the same line of inquiry shall require an explanation as to why the infant was subjected to the manifold dangers of artificial feeding?

It has long been claimed, partly from inference and latterly as a result of milk examinations, that breast milk is not constant in its composition, but varies normally, not only in the total amount of solids, but also in their relative percentages. The admirable work of many milk analysts, especially that of the Adriances, shows some of these variations in solids during the entire period of lactation in quite a large number of recorded cases. So far as I can learn, however, no extensive record has been kept as to the influences of season on the various constituents of the mammary secretion. From my own observation I am confident that careful work will show diminution in the solids of high caloric value during the hottest weather.

A fact which admits of no discussion is this, that dietetic changes to meet the varying thermic conditions of climate and season are essential to normal metabolism in older children. Under what age this physiologic law is inoperative the most exacting artificial percentage feeders have neglected to state. Beginning with as low solids in their synthetic imitation of mother's milk as will sustain life, the rule is to increase gradually all the solids until an approximation of breast milk percentage is attained—the advancing age of the infant requiring a daily increase in the total quantity ingested. Whether from May to September or from October to January, whether in Florida or in Manitoba, the artificial emulsion must be pushed with increasing age. The sweltering infant's cry of thirst is inexorably met with the bottled emulsion of higher proteids and hydrocarbons until the overtaxed digestion suddenly fails. Fermentation and putrefaction follow with acute intoxication and much speculation as to the etiologic rôle played by the organism of Shiga.

Under such dietary regimen of unnatural foods, unnaturally administered, we cease to wonder at the high death rate of bottle-fed babies in hot weather.

When a tithe of the work that has been expended to cheat the babe and mother out of their mutual rights by the substitution of artificial methods of feeding, shall have been devoted to the problem of lactation, its physiology and its pathology, then will the morbidity and mortality of the suckling cease to be the opprobrium of the medical profession and the Shiga bacillus, with its pathogenic congeners, may be relegated to the background.

SUGGESTIONS FOR REDUCING THE PREVALENCE OF SUMMER DIARRHEA IN INFANTS.*

J. ROSS SNYDER, A.B., M.D.
Physician to Children of the Outdoor Poor for Society of United Charities.
BIRMINGHAM, ALA.

Summer diarrhea is caused by the entrance into the system, usually through some food medium, of a virulent poison, which is the product of micro-organisms.

The symptoms in a given number of cases of summer diarrhea will vary enough to enable one to recognize, aside from degrees, several forms of the disorder.

The nature of the infection—whether it was poisonous products already formed outside the body or whether it was bacteria as such that entered the gastro-intestinal tract—has been offered in explanation of this variation in symptoms. But since, thus far, there has been no single form of bacteria separated as being specifically responsible, it is possible that the nature of the organism itself has something to do with shaping symptoms.

However, what uncertainty exists as to the cause of the several forms of the disease does not make less absolute the conviction in the minds of bacteriologists that summer diarrhea is the result of bacterial infection and that whatever other factors are concerned are not causes *per se*, but are only conditions most favorable to the development of the bacteria and to the production of their poisons.

It was by accepting this view that Kerley[1] was able to prove so brilliantly the curable nature of the disease.

But summer diarrhea is better than curable—it is preventable. If a child is fed on a food containing neither poison nor organisms capable of producing poison that child will not be poisoned!

We witness, however, an annual recurrence of this disorder and in such prevalence as to show that we have thus far accomplished but little in the way of prevention. This unsatisfactory result is easily accountable.

First, because there is a large percentage of practitioners still believing that heat and humidity alone and without the presence of a single bacterium are capable of producing the disease.[2] This view precludes any acceptance of its preventable nature. Consequently, a large percentage of the medical body has shown no inclination to co-operate with those especially interested in carrying out prophylactic measures.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M McClanahan, A. C. Cotton and H. E. Tuley.

[1] Kerley: "Treatment of Summer Diarrhea in Infants." New York Medical News, Aug. 4, 1900.

[2] Editorial: "Summer Diarrheas in Children." THE JOURNAL A. M. A., July 4, 1902.

Beside, there is involved in the subject of prophylaxis itself a complexity and a multiplicity of questions that have been discouraging to the accomplishment of appreciable results. Once we undertake to force the right of every child to receive nothing but a clean unpoisoned food we find ourselves entangled "in embarrassing questions of home sanitation and of personal hygiene and in graver questions of state medicine and of public charities."

Another factor, which has offset any results in the way of general prophylaxis, is found in the increase in the number of children being artificially fed. The artificial foods are the ones most likely to be contaminated and the artificially-fed infant offers the least resistance to bacterial poisoning.

Realizing, then, the main difficulties confronting us, can we overcome them?

Since the whole question, complex as it may seem, resolves itself into one of education, it seems to the writer that these disorders ought no longer to be accepted as inevitable.

The persistent pushing of the infectious nature of summer diarrhea at every available opportunity by every member of the profession who believes in it, and especially by every member of this Section who believes in it, will soon have the profession at large educated up to the point of acceptance. Let the bacterial origin of the disease be taught in our schools, stressed in our societies and our journals, and there will soon be found as few retaining the old ideas relative to the cause of summer diarrhea as there are now still holding to the old ideas of the cause of puerperal septicemia.

MODE OF ENTRANCE OF BACTERIA.

The food of the ordinary infant is milk. Unfortunately milk is one of the happiest of media for bacteria. Breast milk is not infrequently contaminated through careless and uncleanly habits of the mother. Therefore, we find that summer diarrheas are not confined entirely to bottle-fed babies. But owing to carelessness in dairy methods, in its transportation and in its handling, cow's milk is much more apt to be contaminated with enough of adventitious matter to make it swarm with microorganisms. Notwithstanding, I meet doctors prescribing milk formulæ who do not even take the trouble to ascertain the name of the dairy furnishing the milk from which their formulæ are to be made. In a community above the average in the intelligence of its medical men, I find the utmost indifference as regards the milk supply. To a large body of the profession milk is milk. Our duty here is clear, namely, to teach these men that some milk is milk and that some milk is—poison!

PERSONAL INSPECTIONS OF DAIRIES.

The result of this teaching will be more general inspections and investigations of dairies by physicians. The physician, who possesses any degree of progressiveness or any regard for the welfare of his patients, will come to appreciate the advantage of being able to recommend dairies which are reasonably certain to supply clean milk. This is a commercial age, and dairymen, without being necessarily dishonest, are governed by commercial motives. There can be no greater stimulus for getting dairymen to exercise care and thought in an endeavor to supply an uncontaminated milk of good quality than the knowledge that what they give will be known and that their prices and patronage will be governed somewhat by the quality of milk furnished.

MILK COMMISSIONS.

Even should there exist among medical men a widespread desire to raise the milk standard, except for those physicians living in towns where the milk is furnished directly to the consumer by the dairyman, the visiting of dairies and the inspection of conditions thereon would be found to be impossible. In large cities milk is furnished by dealers after it has been collected from many farms and from varying distances. For the individual physician to inspect the source of such a supply is clearly impractical. This difficulty has already been partly met in some few cities by the establishment of what are known as milk commissions.

The objects, methods and personnel of such a commission, briefly stated, are about as follows:

The commission assumes the responsibility of ascertaining and of recommending dairies and dealers which can be depended on to furnish clean milk. On request, any dairyman or dealer is furnished with explicit instructions as to how he may bring his dairy or depot and its product up to the requirements of the standard set by the commission. Should he become a candidate for the certificate of recommendation furnished by the commission, his farm in the one case or his milk depot with its source of supply in the other, is inspected and the certificate granted or refused, according to the findings. Any certified dairy is open to as many inspections and without previous notice, as the commission may see fit to make. The commission withholds the right to withdraw any certificate issued.

Beside members, whose duties are purely executive or clerical, the commission is usually composed of four experts: (1) A veterinarian, who examines the cattle and all matters pertaining to their health, care and management; (2) a physician, who examines all persons connected with the dairy in relation to their habits of cleanliness as well as for transmissible diseases; (3) a bacteriologist, who examines the milk to test the efficiency of the measures in force for excluding bacteria, and (4) a chemist, who examines the milk as to its composition and for adulteration.[3]

WHERE MILK COMMISSIONS HAVE FAILED.

These commissions have accomplished enough to prove their practicability and to encourage those interested to further endeavor, but their results have not been in proportion to the unselfish efforts that have been expended. This disappointing feature is due to a lack of appreciation and of co-operation on the part of the general profession. The men interested in such commissions are too often regarded as enthusiastic cranks possessed of a hobby! They even fail to gain the undivided support of those directly concerned with the question of infant feeding. A partial canvass by the writer of the nurseries and babies' hospitals in one of the cities having a milk commission, resulted in the finding that not a few of these institutions were employing milk other than that recommended by the commission.

I believe this failure of the profession at large to take early advantage of the benefits offered by the milk commission to be due in part to the sectional workings of the medical societies of large cities. It is only the most energetic and progressive man in such societies who is

---

[3] For fuller description of milk commissions see reprint from seventeenth annual report of Bureau of Animal Industry (1900), entitled "Market Milk: A Plan for Its Improvement," by R. A. Pearson, M.S. I have made free use of Mr. Pearson's description in this article.

THE WEIGHT WAVE OF MENSTRUATION.

A PRELIMINARY NOTE.

WM. T. BELFIELD, M.D.
CHICAGO.

The record of the daily weight of four healthy, unmarried women between 22 and 29 years of age, and of average menstrual regularity, during a total of twenty-three menstrual periods, discloses a phenomenon which I have termed the weight wave of menstruation. This comprises the following features:

1. During several days, especially the first, preceding the menstrual flow, there occurs a progressive increase in the weight of a healthy young woman, often comprising—especially in winter—from two and one-half to five pounds, which may be from 1½ to 5 per cent. of her usual weight. The climax of this gain is immediately followed by the rapid loss of a large part, perhaps half, of this increase in weight (often within eight to sixteen hours) and then a more gradual loss of the remainder, extending over several days (Fig. 1).

FIG. 1

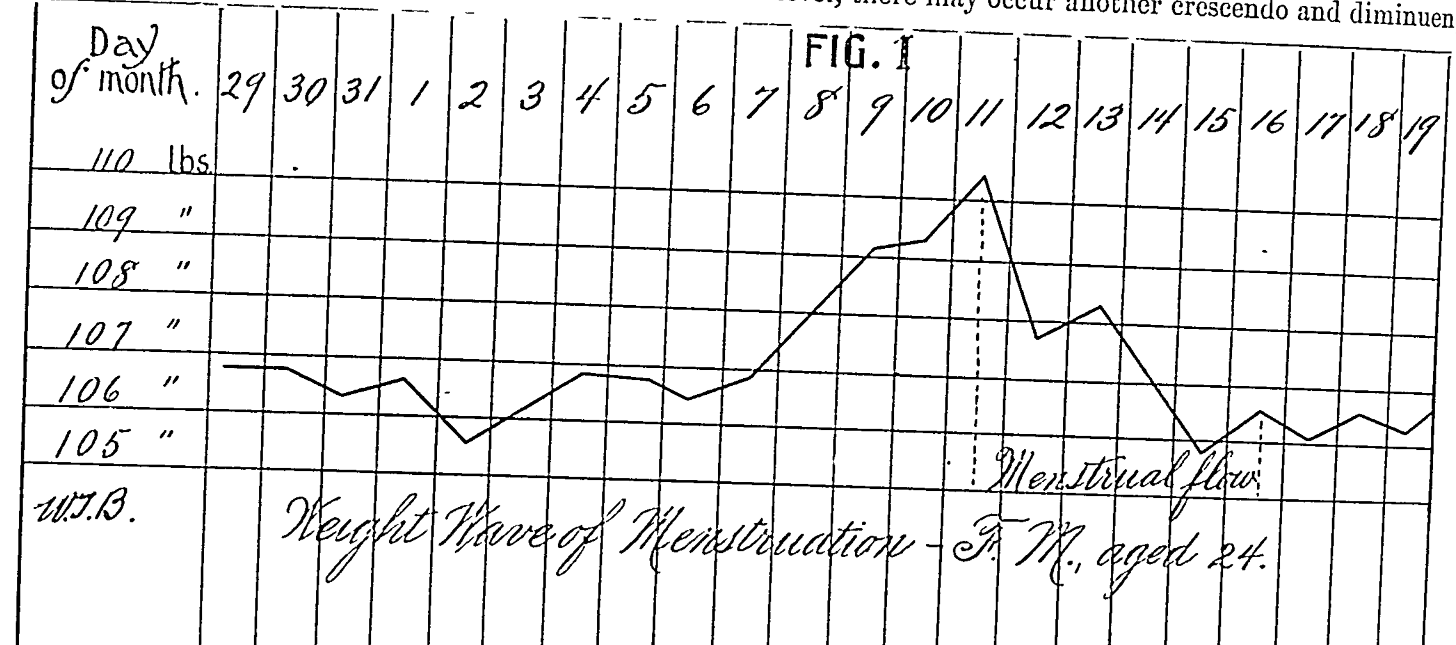

FIG. 2

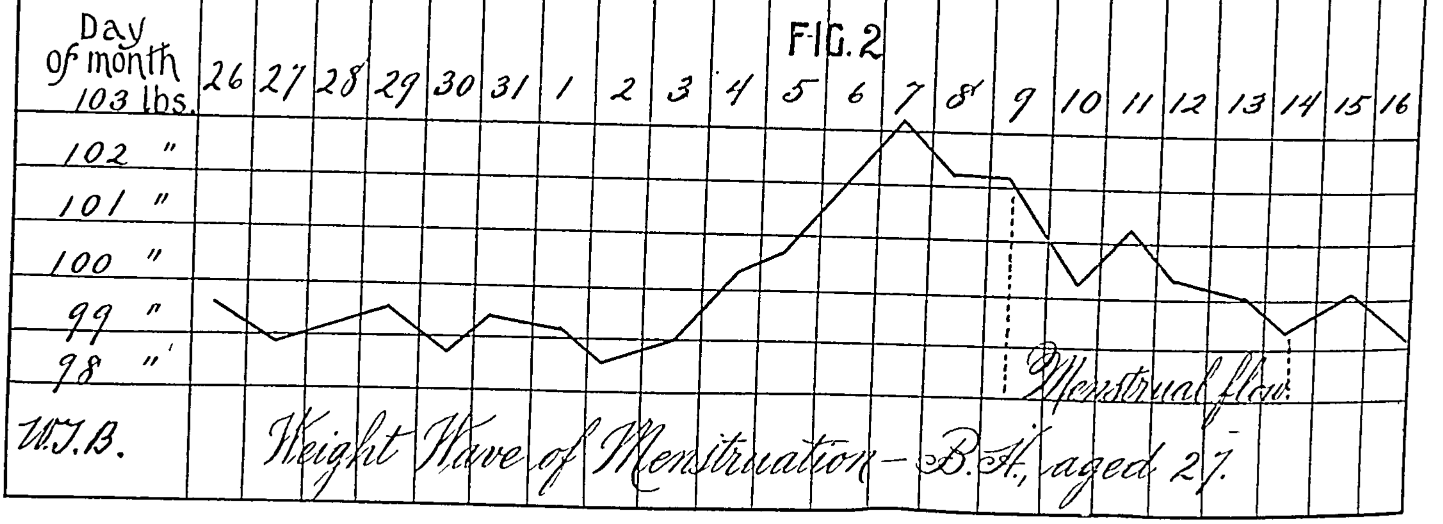


2. The menstrual flow begins during the rapid loss of weight mentioned, the appearance of the blood often, though not always, following immediately on the crest of the wave. The flow continues with the less rapid loss of weight during the next few days, terminating about when the woman's weight regains its pre-menstrual level (Figs. 1 and 2).

3. The pre-menstrual gain in weight is due, not to increased ingestion of food, but to diminished excretion, especially of water. The rapid loss of weight following the crest of the wave is due, not to abstinence from food (nor, of course, to the trifling loss of menstrual blood), but to rapid excretion, notably of carbon dioxid and water. Thus I have seen a woman lose two and one-half pounds in weight during the five hours following the appearance of the menstrual flow, though neither urine nor feces had been voided during that period, and though the subject had had no exercise other than that incidental to clerical office work. (Her loss of weight during the same period, between menstruations, averaged less than one-half pound.)

4. The appearance of the menstrual blood does not always coincide with the beginning of loss in weight; the flow may begin before or, more often, after the loss of weight becomes distinct (Fig. 2).

5. After the weight has sunk to its pre-menstrual level, there may occur another crescendo and diminuendo movement, lasting several days, but less pronounced and typical than the menstrual wave. Hereafter the weight shows no constant variation until there occurs a sudden, transient loss, which is the frequent forerunner of the next menstrual wave.

6. A girl of 14 and a woman of 23, both of irregular menstrual habit, exhibited the menstrual weight wave on several occasions when the flow was nearly or quite lacking.

7. A woman of 59, who had not menstruated for twelve years, showed no weight wave characteristic of the menstrual period in young women.

8. For two days preceding the climax in weight there is often marked torpidity of the bowels and scantiness of urine; while, with the decline in weight, excretion

by bowels and kidneys, as well as by skin and lungs, is notably increased.

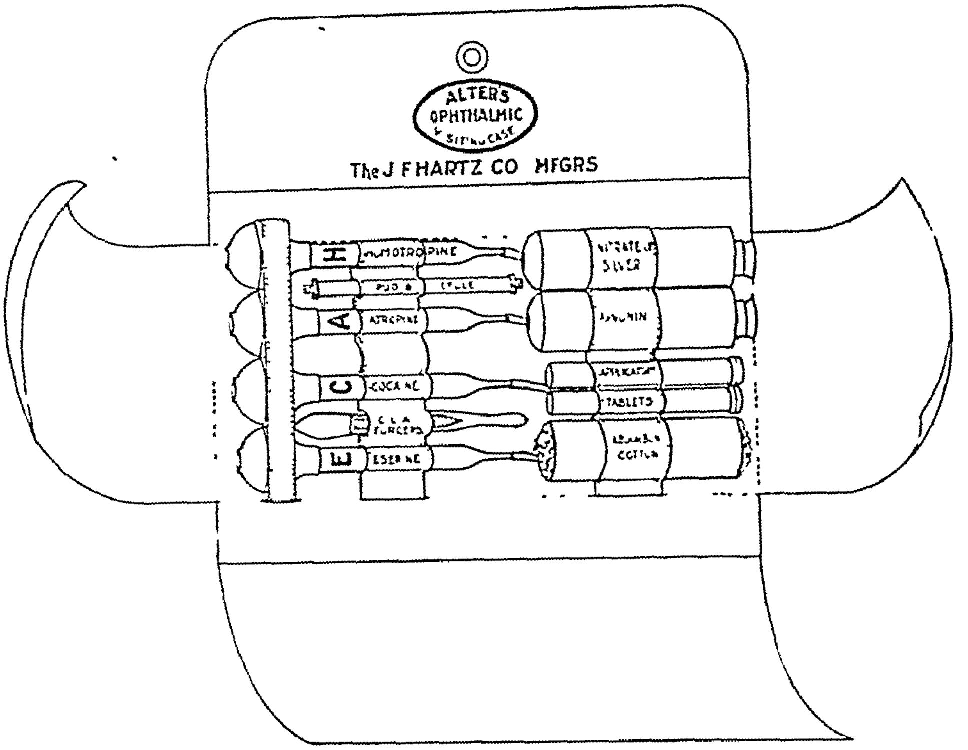
9. The temperature curve is not constant; there is usually a rise of about 1 F. during the increase in weight and a sudden fall after the crest of the weight wave is passed.

New Instruments.

A NEW OPHTHALMIC VISITING CASE.

FRANCIS W. ALTER, M.D.
TOLEDO, OHIO

This little visiting case which I present to the profession and which is herein portrayed is of especial interest to oculists; it can of course, be used by the physician in general work in connection with his ophthalmic cases.



As will be seen by the cut, it contains all the essentials commonly used in the treatment of eye cases, each dropper being marked in a manner indicating its contents.

The case contains cocain, atropin, eserin, homatropin, two bottles of silver nitrate in different strengths, a phial for toothpicks and a reservoir for cotton, beside a bottle intended to hold a relaxing tablet, a spud and a pair of epilating forceps, a pocket in the side of the case for prescription blanks, cards, etc. While the case is primarily intended as a visiting case it serves all purposes for office work.

338 Summit Street.

A POCKET STERILIZER AND INSTRUMENT CASE

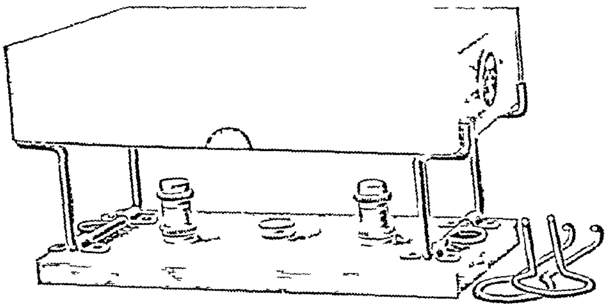
W. P. HERRICK, M.A., M.D.
NEW YORK.

The object in devising this case was to do for minor and emergency surgery what the compressed tablet has done for minor and emergency medicine. When closed and packed the case measures 7x3½x1½ inches or 17.5x8.5x4 cm., thus being easily portable in the breast pocket or emergency bag.

A telescope cover (see cut) gives an extra sterilized tray for instruments after boiling. The box itself being the boiling tray, both of these are manipulated, when hot, by the handles, the boiling tray by holes in its upper edge on either end, the cover by its edges, and the instrument tray proper by its wire handles. Thus we have a sterile field, with three trays, produced in one boiling.

As an instrument case, the instruments are packed in the instrument tray, held in place to prevent rattling or damage by spring crossbars caught in perforations of the tray on either side. This I believe is a new feature and thus the instruments are easily placed in the tray, the spring clips holding them, whether more or less are carried, as individual selection dictates. The instruments are all of standard size, a considerable convenience in operating not possessed by many pocket instrument cases. This selection approximates the usual hospital routine as follows: dissecting forceps, probe, small curved scissors and Kocker clamp, scalpel, artery clamp, Abbe needle holder, spool of silk and needles carried in a small needle box which also holds the sodium carbonate for boiling, Volkman spoon, director with aneurism needle handle and curved bistoury. If needed, the Kocker clamp and Abbe needle holder may be used with the artery clamp for hemostasis, thus giving three clamps, and for blunt extraction the aneurism needle and tray handles may be used. For minor and emergency surgery the above should be amply sufficient.

The essential part of the sterilizer is the double wick alcohol lamp, measuring 6½x3¼x½ inches, or 16.5x8.25x1.2 cm., having a capacity of about 80 c.c., a little less than three fluid ounces of alcohol, and thus can burn several hours steadily. When the boiling tray is half full of cold water, the usual amount, the boiling time is ten minutes. This will not be found excessive, however, as after lighting the lamp the preparation of the patient and sterilization of the hands will fully occupy it. With hot water the time is, of course, reduced proportionately, or the boiling tray may be placed on a gas stove or range, as in an ordinary sterilizer, should this be desirable. The wicks are covered by screw caps, as is the filler and vent when not in use, and folding legs support the boiling tray, which is kept from being knocked off in any way by the holders.



There are many other convenient surgical uses to which this case can be put, as in catheterization, or in clinic dressings; having continuously boiling water at your hand the instruments may be dipped as one passes from case to case, while with slight modifications of size or shape it would be all sufficient for many other surgical manipulations or operations of several of the specialties. Its cost will not exceed $6.75, exclusive of instruments, which is no more, I believe, than any first class ordinary metal pocket case would cost.

IONS AND ELECTRONS.

Among the new words emerging from the laboratories of physics and chemistry which are finding their way into articles on medical subjects are "ion" and "electron." The word "ion" is already well launched medically; the word "electron," though but seldom met with as yet in contributions to the medical press, is destined to occupy, sooner or later, a very prominent place in medical writing. It seems worth while, therefore, to try to make the meanings of these words clear in order that those of our readers not quite at home with them may have less difficulty in understanding the articles in which they may chance to be used.

Bearing firmly in mind the conceptions of atoms and molecules gained in our chemical studies of the past, it is not difficult to pass on to the idea which the term *ion* has been adopted to express. After the establishment of the molecular theory, chemists soon made observations which led them to believe that they had to deal with particles which, on the one hand, were different from molecules and, on the other hand, possessed properties not pertaining ordinarily to atoms. It had been known for a long time that aqueous solutions of some chemical substances (e. g., sodium chlorid, hydrochloric acid, potassium hydrate) will conduct electricity, while those of others (e. g., sugar) will not. The substances, aqueous solutions of which will conduct, are called electrolytes. They are altered by the passage of the current, decomposing on electrolysis into certain constituents which become separated, one going to one electrode, the other to the other. Faraday showed that when a current of electricity acted on solutions of different salts, equivalent quantities of the metals are deposited by the same current in the same time. All inorganic salts are electrolytes, as are acids and bases. The hydrogen of acids always becomes separated at the negative electrode, as do the metals of salts, while the rest of the acid-molecule or salt-molecule becomes separated at the positive electrode. It was thought, at first, that the passage of the electric current determined the decomposition of the dissolved substance, though Clausius (1857) assumed that some of the molecules of an electrolyte are dissociated into their ions (kation and anion), and that these move independently of one another. The part of the dissolved substance that goes to the negative electrode was called the *kation,* while the part that goes to the positive electrode was called the *anion.*

The Dutch chemist, van t' Hoff, a little more than fifteen years ago, drew attention to the relation between dilute aqueous solutions and gases. Pursuing his studies further, he was able, in 1895, to apply Avogadro's law for gases to solutions and to make it almost certain that solutions having the same osmotic pressure, at the same temperature, contain the same number of molecules. But just as certain vapors, like ammonium chlorid, exert a greater pressure than would be expected according to Avogadro's law, so van t' Hoff found that certain substances in aqueous solution similarly "disobeyed" the law; these "irregular" substances are all electrolytes, non-electrolytes are "regular."

An explanation of the exceptions to Avogadro's law for gases like ammonium chlorid had been found in the suggestion that some of the molecules break up into a molecule of ammonia and one of hydrochloric acid; such a dissociation would cause an abnormally large gas pressure. Then came the epoch-marking paper of the Swedish physicist, Svante Arrhenius, in which the theory was advanced that in solutions of electrolytes the abnormally high osmotic pressure is due, not to a breaking down of molecules into smaller molecules as in the case of ammonium chlorid vapor, but to the dissociation of molecules into *ions,* each ion being an atom, or a group of atoms, charged with electricity. Thus, according to Arrhenius, in dilute aqueous solutions potassium chlorid is dissociated into potassium ions (kations) and chlorin ions (anions). The ion is entirely different from a molecule or a neutral atom; it carries an electric charge. The degree of dissociation in a solution can be quantitatively measured by establishing its electrical conductibility. In a concentrated solution of potassium chlorid there is but little dissociation; the substance is present in the water chiefly as KCl molecules and there are but few ions. In a very dilute solution the dissociation is great; there are few KCl molecules present, but an enormous number of ions. Dry copper sulphate is white or about colorless, for its molecules are colorless; dissolve it in water and the solution is blue, for copper ions are blue. Sugar does not become dissociated (ionized) when it is dissolved in water; hence solutions of sugar do not conduct electricity.

Again, when a substance is dissolved in water, the freezing point of the solvent is lowered. Certain substances had been found by Raoult to cause abnormally great depressions of the freezing point, and it turned out that they were the same substances which yield abnormally high osmotic pressures. The theory of Arrhenius of electrolytic dissociations explains these abnormalities wholly satisfactorily, as well as certain other abnormalities of the lowering of vapor tension of solvents, which need not be gone into here.

The development of the ionic theory has made many old facts turn new faces to us. The vast majority of chemical reactions prove to be reactions between ions, not between molecules. When HCl is neutralized with $NaOH$, the molecules are first dissociated into their ions and the reaction consists in the union of the hydroxyl ion of the base with the hydrogen ion of the acid to form water, the sodium and chlorin ions remaining as ions in a dilute solution of sodium chlorid. The effect of salt solutions on the heart muscle seems to be due entirely to the action of the sodium ion, the chlorin ion being inert.

But chemists and physicists had still a step further to go, and the step has turned out to be a great leap. Investigators began to ask "What is the explanation of the electric charge on an atom which makes an ion so different from a neutral atom or a molecule?" Illumination came in an unexpected way. Years ago Sir William Crookes suggested that the kathode rays in vacuum tubes represent matter in a "fourth state," neither solid, liquid or gaseous. He was smiled at and almost jeered at for a while, but it seems he was right. The researches of J. J. Thomson and others have shown that the matter thrown off as kathode rays, and causing x-rays or phosphorescence where they strike, consists of fragments much smaller than atoms, of ultra-atomic corpuscles of which the chemist's atoms seem to be composed. The lightest atom hitherto known is the atom of hydrogen, but the atom of hydrogen weighs 1,870 times as much as one of these corpuscles. Moreover, no matter what their source is, these ultimate corpuscles appear to be identical. The name *electron* had been given to the electric charge on an ion by Dr Johnstone Stoney, it is now believed by many that the difference between an ion and a neutral atom lies in the presence or absence on the atom of one of these ultimate corpuscles of Thomson, so that the name *electron* is now applied to the corpuscle. To some of the wonderful properties of these extremely minute electrons we expect to call attention in a subsequent number.

THE TRYPANOSOMA DISEASES

That some controversy has taken place concerning the priority of the discovery of the trypanosome as a pathogenic blood-infesting organism in man, denotes a well-grounded suspicion that this flagellate protozoon and the disease it produces, trypanosomiasis, may in the course of time occupy an important position among the infectious diseases common to man and the lower animals. In veterinary science the trypanosome has long been known as a potent agent of disease causing ravages of great economic consequence among cattle, horses and other domestic animals. In different countries the disease has received names more or less colloquial, and it does not appear to be definitely settled which of these may be due to identical or different trypanosomes. The nagana of Central Africa and the Transvaal is believed by Laveran and Mesnil[1] to be caused by the same organism as the mal de caderas of South America, although this requires further study for confirmation.[2] Koch, Nocard and others have expressed the belief that the trypanosomes of nagana and surra, the designation the disease has received in the Orient, are also identical. Theiler has recently reported a new trypanosome affecting cattle of the Transvaal which, unlike that of nagana, is non-pathogenic for other mammals; it also possesses differences of size and structure.[3] The discovery by Dutton of trypanosomiasis in man in the instance of an English government official and the report by Manson[4] and Maxwell-Adams[5] of other similar cases furnishes a forcible illustration of the valuable information to be derived from a study of tropical diseases."

It is generally believed that in animals the disease is communicated by the bites of insects, nagana being widely known as the tsetse-fly disease, in dourine, the trypanosoma disease of cattle in Algeria, the adjacent European countries and Turkey, coitus furnishes the means of transmission of the disease from one animal to another and the first lesions appear on the genitals. The case of human trypanosomiasis reported by Manson, a woman and one of the European colony of the Congo region, experienced the first symptoms two or three days after an insect bite on the foot. Trypanosomiasis in animals is characterized by common symptoms, notwithstanding variations in the genus of the protozoa. A profound anemia, edema of the dependent parts, progressive paralysis and disturbances of vision are accompanied by remittent or intermittent fever. Horses and other equines in which the disease has been produced experimentally have died in from a week to a few months; in the Argentine Republic a chronic form of trypanosomiasis has been known under a distinct name, "baacy-poy." The organisms have not been found in the blood of animals ill from baacy-poy, yet such blood injected into healthy animals produces the acute form or mal de caderas. In Manson's case referred to above there was a periodic apyrexia of seven days interrupting a fever lasting three days; accompanying the fever an erythematous eruption developed on the face and trunk.

At the recent session in New Orleans, F. G. Novy demonstrated before the Section on Pathology and Physiology pure cultures of the common trypanosome of rats which had been grown on rabbits' blood serum mixed with agar. The growth occurs in the water of condensation and not on the surface of the medium, as in the case of bacterial growths. The experimental cultivation of an animal parasite on artificial media as a pure culture has not been heretofore accomplished, and great credit is due Novy and his assistant, W. J. McNeal, for the introduction of technical methods affording greater opportunities of studying these parasites.

The points of similarity between trypanosomiasis and malaria in the occurrence of protozoan parasites in the blood producing a destruction of the red corpuscles suggest the application of similar methods of cultivation to the plasmodium. The results of careful, thorough study of an epidemic among rats at Ann Arbor and the discovery of allied parasites in man through researches in tropical diseases, it may be seen from the foregoing, are closely related developments of science and we may confidently expect that the next step, dealing with the prevention of the disease, will soon be taken. It matters little whether horses or rats be first successfully immunized, although the former accomplishment would confer a great benefit, since in horses trypanosomiasis is invariably fatal; the importance of immunization against diseases caused by trypanosoma, in its possible application to similar therapeutic measures in malaria, is at once evident. There are also other possibilities connected with studies of the evolution and development of the parasite, since light may be thrown on the etiology of other infectious maladies, the protozoan character of which has been suspected.

PRESENT STATUS OF TYPHOID FEVER.

The Widal test has narrowed the bounds of typhoid fever very slightly in one direction, but has greatly extended them in many others. Certain febrile affections that run a symptomatic course, absolutely impossible of differentiation from typhoid fever by any clinical observation, however expert, which occur in epidemic form, have rose spots and a continued fever of self-limited duration, and with a tendency to hemorrhage from mucous membrane and enlargement of the spleen, with well-marked liability to relapses that repeat the previous stages of the disease—in a word, exhibit all of the group of symptoms supposedly pathognomonic of typhoid fever now known to be due not to the bacillus of Eberth, but to certain of the bacilli of the colon group. It is agreed that these are not true typhoid, but paratyphoid fever. How wide the limits of this new affection may be is not yet definitely known, but it is generally conceded not to be very common. Its true distribution remains to be decided by actual observation rather than by theoretic considerations. For instance, the very interesting question is now on the tapis whether in certain parts of the south, owing to climatic influences, paratyphoid fever may not be much more frequent than elsewhere, since certain recent observations point in this direction, and because the south has always presented some anomalous types of continued fever not easily reconcilable with the ordinarily accepted type of typhoid fever.

On the other hand, the Widal test has demonstrated with absolute assurance that a number of affections hitherto called by other names are really cases of typhoid. There is scarcely a part of the country that did not have a special continued fever, supposed to be characteristic to itself alone. This was often given a special name, such as mountain fever in the west, so-called camp fever in the east, typho-malarial fever in the south. According to the Widal test, mountain fever is undoubtedly true typhoid. The assumption of a typho-malarial fever in the south, supposed to be an intermediate between typhoid and malaria, has been abandoned. The so-called camp fevers of lumber regions and of military encampments are no longer considered independent entities. Obscure malaria at the north is now acknowledged to be, in most cases, sporadic typhoid fever. The country places, according to the statistics of the last United States census, are not spared any more than are the cities, so that all practitioners must be constantly on the look out for it. It is especially at the extremes of life that, according to the revelations of the Widal test, typhoid fever has proven to be much more common than was hitherto suspected. Even advanced age is no protection against the invasion of the typhoid bacillus, in spite of the atrophy of the lymphatic structures of the intestine, through which the bacillus usually finds its port of entry. A patient's age is no longer considered a diagnostic element for the exclusion of typhoid fever, since typhoid without intestinal lesions is not uncommon, and the Widal test has proven its occurrence even after 70. At the other extreme of life, even nursing infants may contract the disease from infected water given them between nursings.[1] In cities where typhoid fever rages with special virulence, continued fever in children is as likely to be typhoid as in their adult relatives.

In any part of the country and in patients of any ag it is safest for the practitioner to assume, in case o doubt, that a continued fever is typhoid until it is prove to be something else. When continued fever present anomalous symptoms that apparently preclude the diagnosis of typhoid fever, it should be remembered tha the occurrence of other typhoid cases in the neighborhood make the best possible pathognomonic indication in doubtful cases. The epidemiologic rule that when an epidemic exists cases should be considered to come under this head until they can be absolutely proved to be something else, remains the most helpful aid for safe diagnosis. The frank immediate declaration of the existence of typhoid constitutes the best safeguard against the spread of the disease and at once arouses interest as to its possible source, thus initiating effective prophylaxis.

THE FOURTH OF JULY TETANUS EPIDEMIC.

In a short time we shall witness the annual slaughter of the innocents. On the morning of July 5 there will be few communities that will not find recorded in the local paper an account of the sacrifice of some life to the celebration of the day before. The bursting cannon, the premature explosion, the burning building, the bulleted cartridge that was supposed to be a blank, will each claim its quota of victims, not to mention the lost eyes and fingers, the burns and injuries beyond number. Were this all, the record would be bad enough, but after the excitement is over, the glory of the day half forgotten, there will begin to appear scatteringly and, therefore, less prominently, accounts of the children who have succumbed after hours or days of suffering to the tetanus-infected blank cartridge wound.

---

[1] Typhoid Fever in Children. Medical News, April 11, p. 711.

This annual tetanus epidemic is as certain as the Fourth itself, and in the large cities like New York and Chicago it amounts to about one-third of the total annual death rate from tetanus. In Chicago there are usually fifteen to thirty deaths from blank cartridge tetanus each year, while the entire number of deaths from tetanus each year is about fifty. Although there are plenty of other wounds received at this time each year, still the blank cartridge causes nearly all the tetanus infections. It is rare, indeed, that the lacerations from the exploding giant cracker are followed by tetanus. That this is not due to any infectious nature of the blank cartridge itself has been abundantly shown; repeated examinations have demonstrated that they are free from virulent tetanus germs. There can be no doubt that their danger lies in the nature of the wound they produce, and the circumstances under which the wound is received. Street dirt is a favorite habitat of the tetanus bacilli or their spores, and the hand that receives the wound is usually well covered with dirt at the time of the accident. The wad carries this dirt, with its contained organisms, deep into the hand, where the ideal anaërobic conditions exist, even excelling those of the famous nail wound of the foot. In proportion to the number of wounds received there can be no doubt that the blank cartridge wounds are far more deadly than the nail wounds, for they are certainly less common, yet they cause about as many deaths.

We should not forget that most of these deaths are preventable if the blank cartridge wounds are properly treated as soon as they are received. It is a sad fact that the greater number of cases of Fourth of July tetanus occurs in boys who have gone to some physician, not infrequently in a dispensary, who, instead of giving the wound the thorough treatment that it deserves, has superficially cleaned and dressed it. The responsibility here lies with the physician who first sees the wound. A thorough surgical treatment of blank cartridge wounds, supplemented by prophylactic injection of tetanus antitoxin when possible, would save many lives every year.

To accomplish the extinction of Fourth of July tetanus two things are necessary. The first is the enforcement of proper regulations of the sale of firearms and ammunition to minors. In cities where adequate precautions are taken, as in Washington, Fourth of July tetanus is practically absent. After this comes the education of the laity to an appreciation of the danger of this particular sort of injury, and in this the daily paper has a mission that, in a number of instances, it is making a commendable endeavor to perform. If the boy and his parent understand that an extremely large proportion of blank cartridge wounds cause lockjaw they will not be satisfied with anything less than the most thorough treatment, for the ordinary individual has a proper appreciation of the seriousness of this disease.

ANOTHER VICTIM TO PLAGUE INVESTIGATION.

From Berlin comes the news that another investigator has fallen victim to accidental infection with plague, on which he was working. This involuntary martyrdom shows the extreme virulence of the plague bacillus. From dispatches in the daily press it appears that the German government has stopped further investigation in this disease because of the danger of its dissemination. Such curtailment of the freedom of investigation will probably not meet with the approval of the scientific world, in spite of occasional victims to accidental plague. Plague is so destructive a disease that science will not remain content until this disease is fully under control and eventually eradicated. To this end continued investigation is necessary; and investigation can be so safeguarded in specially isolated institutes that all danger of the dissemination of the disease is removed. In such institutes competent men should be encouraged to delve and work by adequate emolument. The investigators should live in the institutes while working with plague, and we feel sure that there will be no lack of competent men who are willing to go on and assume all danger attending the work.

VERY ADVANCED THERAPEUTICS.

A rather curious medical assemblage, judging from newspaper accounts, has lately occurred in Connecticut. The Eclectic Medical Association of that state, which has just finished its session, was the occasion for some rather remarkable medical utterances. In the first place, the president's address, as reported, was peculiar, particularly when he had something to say about the smallpox epidemic or pandemic, which has existed in this country in a mild way for the last two or three years. He took a very cheerful view, indeed, stating—if he is quoted correctly—that smallpox is in reality something to be wished for instead of feared, and giving as his reasons that when it is prevalent we have fewer deaths from it than other diseases, and when it is really malignant we have fewer deaths from other causes. He consequently condemned vaccination, claiming that its use prepares the victim for either another disease or an early grave. There was evidently an attempt at something ultra-scientific at the meeting, as one of the speakers brought out some points which we have never seen mentioned before, and which seem worthy of comment. This speaker remarked that so much had been accomplished with argon in cancerous and other similar troubles that he had been led to experiment also with other newly discovered gases, helium, neon and krypton, and had obtained results far surpassing anything obtained from the x-ray or Finsen light treatment. We did not suppose that these substances had yet been isolated in sufficient quantities to be used to any great extent therapeutically, certainly not in tangible doses. If it had been a homeopath of the high dilution order we could imagine that he might see the possible effects of these substances even as they exist unisolated in the atmosphere and elsewhere.

BLOOD CULTURES IN PNEUMONIA.

The application to the study of pneumonia of modern methods of blood cultures is yielding interesting and important results. The most recent and also the most extensive work in this field is that of Rosenow,[1] who reports finding the pneumococcus in the cultures of the blood of pneumonics during life in 77 of 83 cases. In the 6 cases in which the cultures remained sterile there were good reasons to expect this outcome, because the cultures were made after the temperature had returned to normal; and the conclusion seems to be warranted that when the proper technical methods are used the pneumococcus may be recovered from the blood in all cases of typical pneumonia. This being the case, pneumococcemia in pneumonia can not be regarded as having an unfavorable prognostic significance, as concluded by earlier investigators, who obtained positive results in a much smaller percentage of cases. In obscure cases of pneumococcus infection blood cultures may be of positive diagnostic value. The results of blood cultures in pneumonia also tend to throw new light on the pathogenesis of the disease and its complications. Certainly the occurrence of pneumococci in the blood in practically every case of pneumonia constitutes a satisfactory explanation of many of the secondary pneumococcus localizations in this disease—the endocarditis, the arthritis, the meningitis. Perhaps the question now should read: Why are not these complications more frequent? What is the mechanism that leads to endocarditis in one case and not in so many others? Then again, this pneumococcemia revives the question as to the fundamental nature of pneumonia: Is it a general infection with a local manifestation, or is it a local disease with a secondary bacteriemia? This question can not be answered from the facts at hand. Some light would be obtained, however, if opportunity were presented to examine the blood bacteriologically at the very beginning of the attack, before any local signs are manifest.

Medical News.

ILLINOIS.

Sanitarium Incorporated.—Dr. Sanger Brown and others have incorporated the Kenilworth Sanitarium, with a capital stock of $25,000.

Gift for Neely.—At an informal reception at the Cook County Institution, Dunning, May 30, the employes of the institution presented Dr. John R. Neely, the retiring general superintendent, with a diamond stud.

New Contagious Ward.—The plans for the new $75,000 hospital for contagious diseases, to be erected in the grounds of Cook County Hospital, were submitted to the county commissioners, June 6. The building is to be four stories high, fireproof, and will accommodate 116 patients.

Personal.—Dr. William E. Shasted, Pittsfield, has returned from a trip abroad, and has resumed practice.——Dr. Philip F. Gillette, assistant physician at the Illinois Northern Hospital for the Insane, Elgin, has resigned, and has been succeeded by Dr. Joseph M. Kearney, late assistant at Cook County Hospital for the Insane.

Chicago.

Christopher Resigns.—Dr. Walter S. Christopher has resigned as professor of pediatrics in the medical department of the University of Illinois, College of Physicians and Surgeons.

Tuberculosis Sanitarium Dedicated.—St. Anne's sanitarium for the treatment of consumptives at West Division street and North 48th avenue was formally dedicated by Bishop Muldoon, May 31.

To Fight Smallpox.—The finance committee of the city council has recommended an emergency appropriation of $10,000 to be used in combating smallpox. There are now 39 patients at the isolation hospital.

Fugitive Physician Found.—Dr. Gustaf Adolph Walther, who came to Chicago apparently well qualified, but who soon began to display questionable methods in practice, and who disappeared about eight months ago while under indictment for assaulting a young girl, has been located at Tegucigalpa, Honduras.

Premature Celebration Tetanus.—"Fourth-of-July lockjaw" has begun early this year. During the last five weeks, according to the health department bulletin, seven deaths from tetanus due to firearms, toy pistols and explosions have been reported. There were only twelve all told from similar causes up to the end of July last year and only four in 1901, when the mayor's proclamation was rigorously enforced and the number was reduced from twenty-four in 1900.

Suits.—Dr. Chalmers Prentice has sued the Geneva Optical Company for $12,000, alleged to be due on a contract for the payment of royalties on the sale of retinoscopes.——Mrs. Joel Connor, in a suit filed May 29 against the Chicago Lying-in Hospital and Dispensary, claims that her boarding house business has been damaged to the extent of $10,000 by the proximity of the hospital.——Dr. Moses Furlong and William Higgins have been sued for $25,000 by a German girl, who alleges that she was anesthetized and forced to undergo an operation, the result of which has been a permanent injury to her health.

Drop in Deaths.—The drop in the death rate—amounting to a little more than 21 per cent. less than that of the previous week, to 9.8 per cent. less than the average June death rate of the previous ten years, and to 5.7 per cent. less than that of the corresponding week of 1902—is warrant, says the department of health, for the hope that the murderous mortality of the last five months may be counterbalanced by a minimum rate during the remainder of the year. The 461 deaths reported for the week ended June 6 are 120, or more than one-fourth fewer than those of the previous week, and the rate—12.73 per 1,000 of population—is the lowest for any week since that of Nov. 1, 1902, when the rate was 12.56 per 1,000. There were 31 fewer deaths under 1 year, and 31 fewer over 60 years of age, while the deaths between 1 and 5 years remained the same as the preceding week. Pneumonia shows a reduction of 51 deaths; bronchitis, 5; nervous diseases, 12; heart diseases and violence, 11 each; cancer, 9; convulsions, 7; typhoid fever, 4; influenza, 3; measles and whooping cough, 2 each. The pneumonia deaths are the lowest since the week ended Nov. 29, 1902, and the typhoid deaths the fewest since the week of July 5, 1902—the beginning of the epidemic.

The Hospital Question.—It was announced last week in the daily press that only one hospital in Chicago was operating under a license from the city, and that the others found it impossible to comply with the requirements governing the location of such institutions. In order to secure a license, a hospital must have the "consent of the person or persons who may be the owners or agents of the entire frontage of the four sides of the block in which such building is to be located and the entire frontage of the block on the opposite side of the street on which the building faces." In consequence of the prohibitory nature of this section of the building ordinance, and to test its validity, the commissioner of health requested the city prosecutor to institute proceedings against 46 hospitals which have persistently violated the ordinance in this especial regard. The city council, at its meeting, June 8, passed an ordinance which prohibits the establishment of hospitals for the treatment of the insane, inebriates, drug victims, epileptics, or for contagious diseases, unless a majority of the frontage in the block and the opposite sides of the streets facing the block is obtained. A motion to include maternities in the ordinance was lost. When such hospitals are to be more than two stories high the building must be of fireproof construction. Amendments were referred to the committee on health prohibiting the establishment of such hospitals within 200 feet of a school building, and also to prohibit the use of a hospital for more than one class of patients, and providing breathing space around hospitals to be constructed: Where there are less than twenty beds, fifteen feet on each side of the hospital must be vacant; from twenty to fifty beds, twenty-five feet; more than fifty beds, fifty feet.

MARYLAND.

Scarlet Fever Closes School.—The colored public school at Towson has been closed on account of the prevalence of scarlet fever.

---

[1] Medicine, 1903, p. 435.

Personal.—Dr. P. F. O'Neil, Baltimore, has been appointed assistant to Dr. James M. Spear, secretary of the Cumberland City Board of Health, and has taken charge of the Emergency Hospital there.——Dr. James A. Stevens, Oxford, has been elected state medical examiner by the Medical and Chirurgical Faculty of Maryland, vice Dr. Charles F. Davidson, Easton, who declined re-election.

Baltimore.

May Vital Statistics.—During May 753 deaths and 678 births were reported. Scarlet fever was the most prevalent of epidemic diseases. Pulmonary tuberculosis caused 100 deaths, and pneumonia 71.

Dinner to Osler.—Ex-resident and associate physicians of the Johns Hopkins Hospital gave a dinner to Dr. William Osler, May 15, and presented him with the "Dictionary of National Biography," in 65 volumes.

Personal.—Dr. C. M. Franklin of the Sheppard and Enoch Pratt Hospital has been elected professor of psychiatry in the Woman's Medical College.——Dr. H. Barton Jacobs sailed for Liverpool, June 3.——Dr. William Lee Howard is visiting the psychopathic hospitals in Italy and France.

MASSACHUSETTS.

Boston.

New Roxbury Hospital.—The new Deaconess Hospital in West Roxbury will be 84 by 66 feet and three stories in height, of red brick and terra cotta and is to cost $105,000. It is to be one of a group of buildings to be built later on.

Personal.—Dr. Charles C. Foster of Cambridge, formerly surgeon-major of the Fifth Infantry, has been appointed medical director of the Second Brigade, M. V. M., made vacant by the retirement of Lieutenant-Colonel William H. Devine.

Better Classification of Insane.—At the recent meeting the State Board of Insanity devoted most of its attention to the great need of better classification of the insane of the state and the city. Drs. Jelly, Ayer, Adams, Copp, Howard, Page, Lane, and others, each spoke most earnestly on the great value of separating the curable from the incurable and the mild from the severe cases, as can not be done in the present extremely crowded condition of all the institutions.

A Better Report.—Not for two years and six months has the local death rate touched as low a point as for the week ended June 6, namely, 14.94 per 1,000 per annum. The decrease is general and in no special class or disease—17 deaths occurred from pneumonia, 2 from whooping cough, 10 from heart disease, and 4 from bronchitis. There were reported 31 cases of diphtheria, with 4 deaths; scarlet fever 41 cases, with 3 deaths; typhoid fever 9 cases, with 2 deaths; measles 42 cases, with 2 deaths, and tuberculosis 10 cases and 25 deaths.

NEW YORK.

Taxation of County Medical Societies.—The tax commissioners are to begin suits to test the constitutionality of the law passed by the last legislature exempting from taxation the property of county medical societies.

Buffalo.

Personal.—Dr. Harry Meade has returned from Europe.——Dr. Clawes of the Cancer Laboratory has sailed for Europe, and Dr. Burt C. Johnson is soon expected home from Europe.

New York City.

Columbia Appointments.—Dr. C. A. Herter has been appointed to the chair of pharmacology and therapeutics, Dr. Joseph A. Blake lecturer in surgery, and Drs. Forbes Hawkes and C. A. McWilliams instructors in surgery at the College of Physicians and Surgeons of Columbia University, New York.

No Fees for Health Board Physicians.—The health commissioner having heard that physicians and employes of the health department accepted gifts and fees, issued an order forbidding any physician in the employ of the department to accept a fee for professional services, or for signing certificates or affidavits to insurance blanks from persons with whom he had been brought in contact by reason of his official connection with the department.

Notification of Diseases.—The health department is considering the advisability of greatly extending the present list of reportable diseases. The most important proposed addition to the group of disease in which notification is compulsory, is puerperal septicemia. It is thought that this will serve as a restraint on the midwives. In the other group are those diseases in which notification is compulsory only in the case of institutions, though private physicians are requested to report them for the purpose of accumulating valuable statistical information. This list will probably include influenza, lobar pneumonia, broncho-pneumonia, infectious diseases of the gastro-intestinal canal and parasitic skin diseases. The board disclaims any intention of exercising sanitary surveillance over these diseases in the event of their being made reportable.

PENNSYLVANIA.

Endows Bed.—The will of the late Hannah B. Fry leaves $5,000 to St. Timothy's Hospital, Roxborough, for the endowment of a free bed.

New Buildings.—The new building of the State Insane Hospital, Harrisburg, costing $40,000 will soon be ready for occupancy. The four additional new buildings are soon to be erected at a cost of more than $250,000.

Personal.—Dr. Thomas C. Fitzsimmons of Wilkesbarre has been appointed a member of the commission of the Eastern Pennsylvania State Institution for the Feeble Minded and Epileptic.——At the recent meeting of the G. A. R. of Pennsylvania, Dr. Alfred Smith, Beaver Falls, was made medical director.

Philadelphia.

Increase in Typhoid.—For the week ended June 6, 315 new cases of typhoid fever were reported, an increase of 51 over the previous week.

Board of Education Appointments.—Dr. Charles S. Turnbull has been appointed a member of the board of education, to fill the vacancy made by the death of Dr. Thomas G. Morton. Dr. T. J. Buchanan has also been appointed a member of the board.

Early Phthisis Sanatoria.—Director Martin has a plan for establishing, for the summer, sanatoria in Fairmount Park where children of the tenement districts and persons in the early stages of phthisis may be cared for. It is the purpose to enlist charitable organizations in the work, the department exercising general supervision over these field hospitals, and furnishing certain supplies. The Red Cross Society offers to supply 25 nurses.

President Honored.—At the thirty-eighth annual meeting of the Jewish Hospital Association, held May 31, a portrait of William B. Hackenberg, for twenty-five years the president of the association, was presented to the institution. Dr. Solomon Solis-Cohen made the presentation address. The president pointed out that while the income for the year had been $61,192 the expenditures exceeded this amount by $5,026. Legacies and endowments of $67,127 had been received.

Sanatorium Opened.—The twenty-seventh annual opening of the Red Bank Sanatorium on the Delaware River, a short distance below Philadelphia, took place June 6. Fifteen hundred children of the poor were delightfully cared for on the opening day by this life-saving charity. From the opening until August 31, holidays and Sundays excepted, free excursion boats hourly carry passengers to this river resort. Sick children are freely cared for in the hospital on the grounds and are provided with food and delicacies.

Pure Food Crusade.—B. F. Warren, commissioner of the dairy and food department, has begun an active crusade against adulterated products. Warrants have been served for a score or more of prominent dealers, charging them with selling adulterated lard, and an equal number of warrants have been sworn out for other dealers. Analysis of the so-called lard shows that it consists largely of cotton-seed oil and tallow stearin. A large corps of agents are now canvassing the city, with instructions to prosecute to the fullest extent any violations of the pure food law.

Physical Fitness of Teachers.—The hygiene committee of the board of education has adopted a rule requiring all candidates for teaching positions in the public schools to furnish certificates of physical fitness. The applicant must answer questions as to recent illness, association with cases of phthisis, whether disease of throat, eye or ear exists, and as to the use of narcotics and alcoholic liquors. In addition, a reputable physician must certify whether the applicant has phthisis, leprosy, contagious disease of the skin or mucous membrane, defect of hearing, an irremediable defect of vision, etc.

The Index Medicus.—The College of Physicians recently adopted the following resolutions:

WHEREAS, Through the generosity of the Carnegie Institution, which has pledged $10,000 a year for three years, the *Index Medicus* has been revived; and

WHEREAS, The index is valuable to the profession, not only of America, but of the whole world, and its permanent establishment is of the utmost importance to the profession at large; and

WHEREAS, If the profession does not support this publication by a generous subscription it can not be expected that the Carnegie

Institution will continue to defray nearly the entire expense of its publication; therefore,

Resolved, That the College of Physicians requests each fellow, if within his power, to subscribe for at least one copy.

Against Impure Milk.—Dr. A. C. Abbott, chief city bacteriologist, who entered on his duties as chief of the bureau of health, June 1, has begun a campaign against impure milk. Additional inspectors are to be provided. The condition of milk shops are being investigated, and a number of dealers have been ordered to cleanse their places or to close up. It is the purpose to reduce the high infant mortality that commonly prevails during the summer months. A conference of the mayor, Dr. Martin, director of the department of health, Dr. Abbott, and the state veterinarian will perhaps result in a request to the State Board of Health to act in conjunction with the local authorities in regulating dairymen in the handling and marketing of milk.

GENERAL.

Cholera Decreasing.—The recrudescence of cholera in the Philippines is subsiding.

The new board of health of Hawaii organized for work and held its first meeting May 13. President Cooper and Dr. W. H. Mays are the two physicians on the board, the other four are lay members.

Panama Canal Construction.—There are 45 physicians employed to care for the 1,500 laborers and foremen and 160 civil engineers who are now in the pay of the United States, working on the canal at the isthmus. The daily expense of the construction amounts to about $5,000, according to the Chicago *Post*.

Non-Lepers Prefer Life of Ease.—Inmates of the leper colony, Molokai, Hawaii, who are free from leprosy, are unwilling to leave. Some of these went there to care for relatives who have since died. They are not furnished food but live on the hospitality of the lepers. Their removal is attended with difficulty, according to reports by the territorial board of health. A re-examination of all within the colony is ordered by the board to determine who are free from the disease. None, however, wants to leave, because of the easy life and the supply of clothing and food at public expense in a delightful climate, which they now enjoy.

International Hygiene Congress.—The following Committee of Organization for the United States for the Eleventh International Congress of Hygiene and Demography, to be held in Brussels, Sept. 2 to 8, 1903, has been appointed, at the request of the Belgian government, by the Department of State: Drs. E. A. de Schweinitz and A. B. Richardson, Columbian University, Washington, D. C.; Dr. John Marshall, University of Pennsylvania; Dr. Harrington, professor of hygiene, Harvard University. The committee desires to secure the co-operation of all in this country who are engaged in hygienic work, both in attendance at the meeting in Brussels, and in sending papers to the congress. The congress will be divided into two sections, hygiene and demography. The subjects which will be considered are the relation of bacteria and parasites to hygiene, the hygiene of foods, the treatment and prevention of communicable diseases, etc. The important subject of the communicability of tuberculosis will be discussed in its various phases by prominent men. The fee for membership is 25 francs, which may be sent Secretary-General M. le Dr. Felix Pulzeys, Rue Forgeur 1. à Liège, Belgium. Those proposing to attend or send papers will please notify Dr. E. A. de Schweinitz, Washington, D. C.

CANADA.

Large Donations to Cottage Hospital Fund.—On May 17 the Lady Minto Cottage Hospital Fund received $51,000, the following four gentlemen of Toronto each contributing $10,000: Senator George A. Cox, Mr. D. D. Mann, Mr. William McKenzie and Mr. Chester D. Massey.

Isolation of Scarlet Fever Patients in Ontario.—Three months ago the Ontario Board of Health, at their regular quarterly meeting, decided that all patients suffering from scarlet fever must be isolated and removed to buildings or tents specially prepared for them. This stringent measure was deemed advisable owing to the very high death rate which has now prevailed in Ontario for some months from this disease. Several benevolent societies have taken the matter up, as they consider that any regulation which takes a child away from its mother and removes it to a tent, especially in the dead of winter, is inhuman.

FOREIGN.

Yellow fever has broken out at Progresso, Mexico, on the Gulf Coast.

Official Warning Against an Anti-Morphin Remedy.—The Berlin chief of police has issued an official warning against "Nicolicin," a remedy advertised to cure morphin addiction. He states that the principal ingredient is morphin, with a little salicylic acid, and it is thus unsuited to the purpose for which it is sold.

Physicians in Spanish Congress.—The recent elections resulted in the election of four physicians to the lower house and seven to the upper house of the Spanish parliament. Dr. Cortezo, editor of the *Siglo Medico* and president of the Internal Medical Press Association, was appointed vice-president of the upper house.

Norwegian Medical Study Trip.—An attractive program is announced for the trip in August to the various health resorts in or near Norway. The party will gather at Hankö, August 7 and disband the 21st. The total expenses of the trip will be at most less than $50. Dr. S. Meyer, St. Kongensgade 71, Copenhagen, has charge of the trip.

Plague Investigation Stopped.—Because of the death from plague of Dr. Milan Sachs, who was experimenting with the germs at the Berlin Hospital, the government has ordered further experiments to cease, fearing the danger to the public from the handling of the deadly germs. The investigations were conducted in an isolated laboratory and no outsider was allowed to approach.

Consultations for Economic Questions.—The Leipsic "Verband" has organized an information bureau for consultations in regard to all matters affecting the material interests of members of the profession in Germany. A leading legal authority has been appointed consultant. It is especially designed to aid physicians in entering on contract practice or altering their contracts. Advice is free to members of the "Verband" and to local societies which may apply.

Collective Cancer Inquiry in Hungary.—Dollinger of Budapest has undertaken a collective inquiry as to the number of cases of cancer in treatment, October 15, 1903. The step was taken at the request of the government and question blanks have been sent to all the physicians in the country. They are urged to take note of tumors in the animals in contact with the cancer subjects, dogs, cats, cows and horses. The fate of persons previously operated on for the removal of malignant neoplasms is also to form part of the study.

Campaign Against Alcoholism.—An important step has been taken in this line by the German ministers of agriculture, commerce, of the interior and of public instruction, who have signed a joint appeal to the local authorities throughout Prussia urging the establishment of comfortable reading rooms, assembly halls, etc., where workingmen may gather without the necessity or the temptation to buy spirituous liquors. Drinking fountains should be erected and abundant opportunities provided for procuring temperance drinks in the public places and populous streets, and the public should be instructed in regard to the dangers of alcohol on every suitable occasion. The local authorities are requested to report the results in 1905.

Sclavo's Anti-Anthrax Serum Wins the Riberi Prize.—The Turin Academy of Medicine has awarded the Riberi prize of $4,000 to Professor Sclavo for his successful anti-anthrax serum, as the best work accomplished in the medical field during the five years since the prize was last awarded. In a recent communication on the subject Sclavo stated that 293 persons have been treated for malignant pustule with anti-anthrax serum, including a case recently reported by Sanfelice, in which the serum of dogs immunized against anthrax was used. Sclavo announces that a rise of temperature after the injection is a most valuable sign, as it indicates a favorable prognosis as a rule. When the serum is used local treatment is unnecessary, and if administered in time the lesion heals and the edema is spontaneously absorbed. He has found the best method to be a single large dose, slowly injecting 40 to 50 c.c. at three or four points in the forearm or back of the hand. This serum treatment has found a cordial welcome in Argentina, where it has been applied in 130 cases, reducing the mortality to zero except in the moribund cases. Competition for the Riberi prize is open to the world, as previously announced in these columns, but preference is given to a work that tends to improve hygienic conditions in Italy.

The Outlook for the Physician.—Dr. Hofmann, Dillenburg, in a letter to the *Deutsche Med. Wochft.* discusses the outlook for the profession and thinks that the aim of the physician should be to be assured of a comfortable income while reducing the single fee to the lowest possible figure. He thinks that the experience of the duchy of Nassau should prove instructive. It was early appreciated that the health of the populace was a most important public matter and, therefore, all the physicians in the country were supported by the state at a comparatively high salary for those days. The duchy was divided into "medical districts," each with its physician, although the inhabitants were not restricted to employ the nearest. The state paid one-half the income allowed him, and the other half and more if possible he was to make by his practice. The single fee was established by law at fifteen cents for a call in his district, and ten cents for office consultation. The arrangement was considered highly satisfactory for all parties and the profession enjoyed great prestige. In 1866 the duchy lost its political independence and the medical officials their state support, but the medical districts were maintained by the population which paid the physicians a stipend equal to twelve cents per capita on an average, for which he in return treated the poor gratis. The old fee has been retained in some of the districts, but in others it has been increased to a maximum of twenty four cents under this régime. The physician's fee at all times was the same, irrespective of the distance from his residence. Hofmann thinks that some such arrangement outside of the large cities would solve many problems.

Annual Meeting of German Central Committee for Erection of Sanatoria.—The general interest that has been aroused in Germany in regard to the sanatorium treatment of tuberculosis was well illustrated by this recent meeting. The committee has now 1,300 members, including 83 physicians, 6 government ministers, 24 insurance companies, 159 government employes, 344 merchants and manufacturers and 39 business houses with 4 boards of trade. The principal address was by von Leyden, who reported most gratifying results from the movement. In the 74 sanatoria at present in operation 30,000 patients were treated during the year, and 80 per cent. are so much improved that they can be called practically cured He stated that the mortality has diminished from 30.95 per 10,000 in 1875, to 19.50 in 1901. He expatiated on the marked improvement that has followed the organized effort to care for the families when the bread winner is sent to the sanatorium. Gobel stated that the number of persons to whom insurance was paid on account of tuberculosis has increased from 11 to 13 per cent. since 1898, but, on the other hand, the number of pensions paid for non tuberculous affections has diminished by 4 per cent. The ravages of tuberculosis are shown by the fact that out of every 1,000 indemnities paid, 549 were on account of tuberculosis at the age of 20 to 24, 509 from 26 to 29, and 429 from 30 to 34 These figures were for men The corresponding ones for women are 425, 343 and 258. Each patient has cost the national insurance societies 355 marks, about $90, the daily expense being about $1 (4 marks, 69 pfennigs). The length of the average sanatorium course was 79 days. During the last four years the proportion of those dismissed practically cured has increased from 27 to 31 per cent Other speakers urged the necessity of isolation of consumptives and of preventive and curative treatment of tuberculosis in children who are more often affected than hitherto deemed possible Putter advocated that prophylaxis should be along the three lines of education of the tuberculous subject, his isolation as far as possible from the rest of his family in his home and free formalin disinfection.

LONDON LETTER.

Chloroform in the Preparation of Vaccine.

At the Royal Society Dr. Alan B. Green described a method of using chloroform for the elimination of extraneous organisms from vaccine lymph Sterile air is passed through chloroform and becomes saturated with it It is then passed through the vaccine emulsion which has been prepared by triturating one part of vaccine pulp with three parts by weight of distilled water. It is essential that no liquid chloroform be allowed to pass into the vaccine since its presence is strongly inimical to the potency of the vaccine. The vaccine is quickly saturated with chloroform, the excess after saturation escaping automatically. The germicidal action is very rapid, emulsions with as many as 100,000 organisms per platinum loop become free from them in six hours. After elimination of extraneous bacteria in this way the chloroform in the emulsion is evaporated by passing through it a stream of sterile air. Only the non-spore bearing bacteria are killed by this procedure; but in some thousands of vaccines examined in the government lymph laboratories the only spore-bearing organisms found were non-pathogenic. Dr. Green thinks that this method will prove valuable when there is an urgent demand for a rapid supply of vaccine lymph, such as may occur during smallpox epidemics; vaccinations from the lymph so prepared have given excellent results.

The Wounded in Naval Warfare.

At the Royal United Service Institution Dr. Phillip Randall, formerly a naval surgeon, read an important paper on "The Disposal of the Wounded in Naval Warfare." He pointed out that although attempts had recently been made to call attention to the subject there was almost complete absence of it in the works of all the leading authorities on naval warfare. Medical officers viewed with forboding the prospect of being called on to deal with a large number of serious injuries. The conditions of naval warfare have greatly changed since the British navy was engaged in great wars. The sick berth of the present day has gained light and air, but its situation in all modern ships was untenable in warfare. A return to the cockpit principle had been decided on officially for some time, but beyond the selection of a site nothing had been done to make the place suitable. The number of wounded that would have to be dealt with after an engagement should be determined as approximately as possible. After giving figures of some of the battles of the last great wars Dr. Randall said that the working average of 7 per cent. of the complement, as the number of wounded to be expected in each ship, was the irreducible minimum. He then considered the condition of the ship after action, the accommodation provided in naval hospitals on land and the probable distances from such hospitals at which naval action might occur. The one conclusion was that in the fighting line afloat as in that ashore all treatment of the wounded beyond "first-aid" would be impracticable, and further, that after-treatment on board would be practically impossible. The adoption of the principle of hospital ships for fleets would be quite practicable and would go a long way to meet the needs of the situation. Every fleet should have one or more hospital ships attached to it. These would cruise with the fleets, and having first received all cases of serious injury from the ships would accompany them to the verge of safety when they went into action. Each hospital ship should be provided with as many large and roomy boats as it could carry. By means of these endeavors would be made to keep close communication with the fighting line, seizing on every opportunity to collect and transfer to the hospital ship as many wounded as possible.

Correspondence.

The Transmission of Yellow Fever.

HAVANA, CUBA, May 28, 1903.

To the Editor:—Dr. James Carroll, U. S. A., in the paper which he published under the above title in THE JOURNAL, May 23, does me the honor of arguing at great length on my statement that the yellow fever Army board of which he was a member had tacitly denied my rights of priority. I was thus referring to many items of the mosquito theory which the said board had presented to the public as so many new discoveries of their own, ignoring the circumstance that although I had not always been in a position to demonstrate my assertions experimentally, I had included those same items in my theory of yellow fever transmission. Dr. Carroll has indeed now changed the tacit denial into an explicit one, without, however, refuting any of the evidence on which my former statement had been founded. (See my paper in *Medicine*, Detroit, March, 1903, pp. 178 and 179.) I agree with him, however, in thinking that rather than to enter into any controversy it is better to leave the decision to those who will take the pains of reading our respective publications, including, however, one which Dr. Carroll has forgotten, namely, my paper on "Two Different Ways in Which Yellow Fever May Be Transmitted by Mosquitoes," which was published in THE JOURNAL, Nov. 23, 1901. In this paper I have clearly shown that the Army board has never seriously investigated my direct inoculation with recently contaminated mosquitoes. When I had asked them to do so they excused themselves, alleging that they had too few non-immunes at their disposal. This investigation, if favorable to their presumption, would have been the only justification for their attitude of persistent denial that any of my positive results deserve to be taken into consideration. They took the ground that the yellow fever germ must be a parasite of the same nature as the malaria parasite, and that the same rules must be applicable to both. That they were quite mistaken in this last inference I have recently proved in a paper on "Probable Nature and Life Cycle of the Yellow Fever Germ" (see *Revista de Medicina Tropical* of Havana, English text), in which I have demonstrated that although it must be admitted that both germs appear to be protozoa of similar nature and life cycle, yet there is this essential difference between them, that while the malaria germ has the human subject for its permanent host and the anopheles for its intermediate host, the reverse happens with the yellow fever germ whose permanent host is the stegomyia and its intermediate one the human subject. A difference which leaves out of the question such analogies as the Army board has attempted to establish between the two cases.

The phase of development of the parasitic germ which takes place in the body of the mosquito host must consequently be considered as quite different in the two diseases. In yellow fever the interval of time which elapses between the bite of the fresh stegomyia on the infecting patient and the moment when the insect is able to reproduce the disease, in its complete forms, must be supposed to represent the number of days required by the embryo parasites to reach their adult development after they have been sucked up with the blood of the yellow fever patient; but not, as happens with the malaria parasite in the body of the anopheles, the time required for the sexual reproduction of the parasite and for the accumulation of the newly-hatched embryos in the salivary glands of the insect, as the Army board had assumed.

I feel bound, before closing this article, to answer several charges which Dr. Carroll has brought against me. One is, in substance, that availing himself of my present position I have shirked the opportunity of testing my own method of direct inoculation with recently contaminated mosquitoes by obtaining an order forbidding further experiments with mosquitoes having ten or more days of contamination, and only allowing the handling of contaminated mosquitoes to persons well acquainted with the dangers, etc. (See *Medicine, loo cit.*) How Dr. Carroll manages to reconcile his conclusions with these premises I fail to understand, specially if he remembers that there have been only a few imported cases of yellow fever during the last year, and none has originated on the island.

Another charge is that my claims of priority should have been accompanied by unmistakable evidence, in print, as proof that the facts have been demonstrated and duly reported. I have never claimed that I had demonstrated the facts, but I have proved by unmistakable evidence, in print, that I had foretold the results which the Army board afterwards confirmed, giving them as original discoveries of their own.

My table of 104 inoculated persons with recently contaminated mosquitoes (so far as I could judge, operating as I did with insects which were not bred from the larvæ), was handed to the Publication Committee of the Third Pan-American Congress, together with the paper which I read at that congress. Seeing that the publication of the transactions was delayed, I gave a copy of those same tables to Dr. Coronado, who published them in a volume which he dedicated to me and in which were included several reprints from the *Revista de la Asociacion Médica Farmaceutica*. I am sending a copy of this book and also of my paper on "Probable Nature," etc., to THE JOURNAL.

Dr Carroll somewhat sarcastically refers to my humane feeling in having refrained from proving my theory, in my own series of inoculations, for fear of producing a severe attack on persons who had relied on my assurance that no risks would be incurred through my procedure; but he seems to doubt my sincerity because he once saw me apply a fully contaminated mosquito to a non-immune. He, however, carefully silences the circumstance that this non-immune had been informed of the risk that he was incurring, that he had accepted that risk in view of a certain compensation, and that I was induced to perform the experiment believing that it entailed a lesser risk than letting Dr. Calda's assertion go unchallenged when he declared that this same man had been rendered immune through the injection of a secret preparation for the efficacy of which he was trying to obtain our support.

The only part of Dr. Carroll's criticism to which I must plead guilty is the confusion arising from my descriptions of my case No. 3. The second statement to which he refers was made from memory at a time when I had mislaid my original notes. I found them again, however, last year, and ascertained that the experiment had been really made under the conditions which I took the first opportunity of publishing, as a footnote, in the *Revista Médica Farmaceutica*, February, 1902, page 369.

With these explanations I trust that Dr. Carroll and the readers of THE JOURNAL will be satisfied. Dr. Carroll, on the other hand, does not give his reasons for reducing to eight days the *minimum* space of time required for the contamination of the stegomyia while the Army board has fixed that limit at from 10 to 12 days; nor does he present any reasonable grounds for his belief that, *cæteris paribus*, the simultaneous bites of several contaminated mosquitoes should not be expected to produce more severe effects than that of only one of those insects. The Army board, at any rate, is not responsible for these innovations of Dr. Carroll any more than for the charges which he has brought against me.

Apart from such secondary questions, as claims of priority must be acknowledged to be, I must reassert once more my keen appreciation of the invaluable work which the yellow fever Army board has achieved, and I gladly recognize that all the arguments on which my recent paper on the life cycle of the yellow fever germ are entirely founded on the findings of that board. I also beg to express my deepest sympathy in the untimely death of its accomplished and enthusiastic chairman, Dr. Reed, and in that of Dr. Lazear, who was probably the first American convert to the mosquito theory and died a martyr to his scientific zeal in the course of its investigation.

CARLOS J. FINLAY, M.D.
Chief Sanitary Officer of Cuba.

HAVANA, CUBA, May 30, 1903.

To the Editor:—Being the only other survivor of the Army yellow fever board which demonstrated beyond further doubt the transmission of that disease by the mosquito *Stegomyia fasciata*, I may be permitted to record a few facts in connection with said investigation, and in refutation of the openly-made or implied assertions by my learned colleague and late coworker, Dr. James Carroll, Washington, D. C., published in THE JOURNAL, May 23, 1903.

The omission of my name in the early part of the article referred to, where mention is made of Drs. Reed and Lazear, loses its importance before my eyes, when, on continuing the reading of the text, I find it directed principally in a fruitless endeavor to assail Dr. Finlay's right to the honor of the discovery of the only known way by which yellow fever is transmitted.

Aside from this attack on Dr. Finlay's claims, all that appears in Dr. Carroll's paper has been published before in the various articles presented by the Army board by Drs. Guiteras, Gorgas, Ross and myself. (*Revista de Medicina y Cirugia*, Habana, Agosto, 1901.)

Before going further I desire emphatically to affirm: That I was present when the question of following out Dr. Finlay's mosquito theory was brought up by the Army yellow fever board, as it was my right and duty to be, and as it is recorded in our Preliminary Note (reprint from the proceedings of the twenty-eighth annual meeting of the American Public Health Association, October, 1900). That, at that time, neither Drs. Reed, Carroll nor myself believed in said theory, the only one of us inclined to consider it favorably being my friend and classmate, Dr. Jesse W. Lazear. That the work in the lines of Finlay's theory was undertaken as a matter of course, from the fact that a thorough investigation into the etiology of yellow fever was expected of our board, and not because as a body the board thought any too well of it. That of us all, Dr. Lazear was the only one at the time prepared to initiate the work in this direction he being thoroughly familiar with the anatomy and biology of the culex and conversant with the technic required; he had already bred numerous varieties in his laboratory at Camp Columbia, and had been sending specimens to Dr Howard, entomologist, Department of Agriculture, Washington, for aid in identifying the different species That Dr. Lazear was the member of the board, Dr Reed being absent in Washington, who produced our first two cases by the bites of mosquitoes, in the persons of Dr Carroll, who, being an unbeliever, allowed him to apply one mosquito on August 27 and an American soldier, who was bitten by the same insect, and three others, Aug 31, 1900. That Dr. Lazear, not content with this and not in ignorance, for he had suggested to me that the origin of Carroll's and the soldier's infection was, deliberately allowed himself to be bitten by a mosquito while in one of the wards of the yellow fever hospital (Las Animas) September 13, at a time when Carroll and the soldier were convalescing from their attacks I am convinced that this mosquito produced the infection which caused his death Sept 25, 1900

Major Reed was summoned from Washington and the investigation was then undertaken exclusively on the mosquito theory

These are the facts which I deem necessary to make known for the present

No one can regret more than I the circumstances which may have led Dr Finlay to regard the stand taken by the Army yellow fever board as a "tacit denial of his rights to priority", but his false interpretation of our writings could have never induced me to demean the achievements of this "grand old man" Neither the Army board, Dr Carroll or any one can deprive Dr Finlay of the glory of his discovery What matters it, and what wonder is it, that he could not impart to the near-sighted all that he knew when we consider that he lacked the necessary technical training and the material means which were so bountifully placed at our disposal for the demonstration? If he did not indeed convince us at the time that the mosquito was the only means of propagating the disease, are we not convinced of it to day And is it not the same mosquito to which he pointed?

Had we followed out his suggestions for clearing the city of yellow fever (*New York Medical Record*, May 27, 1899), and which were later put into practice with but little variation by Major Gorgas the date of our liberation from the scourge would have been anticipated by three years

Dr. Carroll says

> It is too late after facts have been proved and recorded by others, to claim priority unless one can point to unmistakable evidence in print as proof that the facts have been demonstrated and duly reported

According to this, Dr Finlay undoubtedly is entitled to priority, he demonstrated to himself and reported long ago the true facts of a fundamental principle, which the Army board, by its superior advantages, demonstrated more convincingly to the world ARISTIDES AGRAMONTE, M D

The Library of the El Paso County Medical Society.

DENVER, June 1, 1903.

To the Editor —There are but few cities in the United States with a population of less than 25,000 that can boast of a medical library. I was, therefore, agreeably surprised to find one in a recent visit to Colorado Springs. It is housed in a separate alcove in the Corbin Library of the Colorado College. It contains over one thousand books, all arranged in alphabetical order by authors under the following classification 1, Anatomy, 2, biographies; 3, chemistry; 4, dentistry, 5, gynecology, 6, hygiene, 7, history, 8, materia medica. 9, medical diagnosis; 10, medical jurisprudence, 11, medicine, 12, miscellaneous, 13, obstetrics, 14, pathology, 15, periodicals and reprints; 16, physiology; 17, reference books, 18, reports; 19, surgery; 20, veterinary All medical journals are arranged alphabetically by titles. Reprints are filed in cases under an approximate classification by subjects. A card catalogue arranged by subjects is placed in the alcove, and an author's catalogue is placed in the card catalogue in the general librarian's office The system of classification adopted by this library is unique in that all the subjects are arranged alphabetically I find it very admirable for a small library. It looks odd at first to find dentistry flanked by chemistry and gynecology, and physiology between periodicals and reference works, but it certainly has its advantages. Once one knows that everything is arranged alphabetically he can easily find what he wants.

All this was surprising enough, but I noticed a neatly bound pamphlet dangling on a ribbon, across which I read the words, "Catalogue of the Library of the El Paso County Medical Society."

All the work, the arrangement classification and cataloging was done, not by a hired librarian, but by a committee composed of busy practitioners, Drs R K. Hutchings, W H Swan, F. L. Dennis and H W. Hoagland This committee has done a noble work which the profession of Colorado Springs will come to appreciate more and more as years go by

The library contains a few old books of interest to the lover of *curiosa*. John Friend's Emmenologia, 1752; Sydenham's works, 1740, and N. Robinson's 'A New Method of Treating Consumption.' There will be not a few who will be anxious to find out something about this "new method," now two hundred years old I will therefore transcribe the full title of the book, which reads as follows.

> A new method of treating consumption, wherein all the decays incident to human bodies are mechanically accounted for With some consideration touching the difference between consumption and other decays that naturally attend old age To which are added arguments in defense of the possibility of curing ulcers of the lungs as also reasons for demonstrating that the irregular discharges of all the evacuations in consumption arise from the resistance of the heart not decaying in a simple proportion to the resistance of other parts

From the title one can gather hints as to the curious contents of the book. By the way, there is another book by the same Johnson on which I would like to spend a few hours, namely:

> A treatise on the virtues of a crust of bread, eat early in a morning fast, to which are added some particular remarks concerning the great cures accomplished by the saliva, or fasting spittle as when externally applied, or when internally given, in the scurvy, gravel, stone, rheumatism and diverse other diseases arising from obstruction

Well, "the virtue of a crust of bread eat early in a morning fast' is an experiment with the effects of which legions are fully acquainted. But of "spittle" applied externally I have heard it used only in cases of violent emergencies and under provoking circumstances C. D. SPIVAK, M D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

DO NEGROES RECOVER FROM PHTHISIS?

ATLANTA, GA, June 2, 1903

To the Editor —I see in THE JOURNAL (May 30 p 1520) that Dr Francis Crosson of New Mexico is desirous of information on tuberculosis among negroes. After fifteen years of large experience with tuberculosis among the negroes on the farm and in the towns, I can not recall a single case in which treatment made the slightest impression Not only were all the cases fatal, but the negro succumbs most readily to the infection, and so rapid is the progress of the disease that death soon claims the victim The peculiar hue of the negro's skin is almost an infallible characteristic of the disease

JOHN E ASHCROFT

CHATTANOOGA, TENN, June 2, 1903

To the Editor —In response to the request of Dr. Crosson of Albuquerque, New Mexico, I observe as follows From a very extensive professional knowledge of the negro, both in public hospital work and in private practice, and covering a third of a century, I have come to the conclusion that the colored race as we meet it in the south, is specially susceptible to the inroads of tuberculosis, primarily, and succumbs to this great white plague very rapidly Indeed, I regard tuberculosis as one among the greatest of the foes of the African under civilization in the United States and if one of this race ever recovered under my own observation, after contracting consumption, I certainly do not remember it now With the profession generally in this southern section of our common country, it is a sentiment that when a negro becomes visibly affected with pulmonary phthisis his doom is already practically sealed and there is a very short period expected to intervene between the victim and his taking off as soon as a diagnosis becomes readily appreciable.

E. A. Cobleigh.

Mobile, Ala. June 3, 1903.

To the Editor:—Some years ago, while assistant superintendent of the Alabama Insane Hospital at Tuscaloosa, I availed myself of the excellent opportunity there offered of studying the relative frequency and curability of tuberculosis in the white and colored races, from both a clinical and pathologic standpoint. The results of my observations were published in the *New York Medical Journal*, Feb. 23, 1895, and may be epitomized as follows: The mortality from tuberculosis is greater in the negro race than in the white. The disease runs a more rapidly fatal course in the negro. General miliary tuberculosis is many times more frequent in the negro. Instances of arrest or cure of tubercular disease are comparatively rare in the negro. Nevertheless, recovery from tuberculosis is not unknown in negroes; I have known two cases.

E. D. Bondurant.

Agricultural College, Miss., June 5, 1903.

To the Editor:—In answer to Francis Crosson's inquiry, I will say that I have known only one case to recover in a practice of 28 years. It is an almost unknown occurrence, and there are many dying in this country from tuberculosis. Tuberculosis with the negro before they were freed was almost unknown. Then they were fed well, clothed well, housed comfortably, made to keep regular hours, and when one was taken sick the very best nursing and medical attention was given him. The kind friends of the negro in the north who are anxious to help him with their money could do him no greater service than to provide a fund to be used in securing him good nursing and first-class medical attention when he is sick. They have one habit that I am not sure they had when slaves, viz., sleeping with their head covered; that adds much to cause this succumbing to tuberculosis.

W. H. Barr, M.D.

Marriages.

B. F. Walker, M.D., Laton, Cal., at Winchester, Ill., May 26.

L. Mae James, M.D., to John J. Houton, M.D., both of Detroit, Mich., June 2.

A. C. Ecke, M.D., Chicago, to Miss Sadie Beaman of Fond du Lac, Wis., May 31.

Charles Edward Terry, M.D., to Miss Marion Stuart, at Annapolis, Md., May 29.

Fred Clifton Honnold, M.D., Riverside, Ill., to Miss Aimee Coulter of Chicago, June 10.

David M. McFall, M.D., Mattoon, Ill., to Miss Fannie Johnson of Quincy, Mass., June 3.

Rowland McFarland, M.D., to Miss Maude Elena La Fergey, both of Daggett, Cal., April 14.

Marion Russell Thomas, M.D., Savannah, Ga., to Miss Ethel Ray Butler of Baltimore, June 9.

Claude Allen Thompson, M.D., to Miss Harriett Pauline Shoenfelt, both of Muskogee, I. T., May 24.

Arthur G. Kessler, M.D., Lyons, Cook County, Ill., to Miss Mary L. Barnum, at Waukegan, Ill., May 20.

Deaths.

Timothy Barnard Chisholm, M.D. Atlanta (Ga.) Medical College, 1861, acting assistant surgeon in the Confederate service; for many years county physician and coroner; a member of the Medical Association of Georgia and of the Georgia Medical Society of Savannah, died at his home in that city, May 7, after an illness of three days, aged 63.

John Newton Dexter Shinkel, M.D. Rush Medical College, Chicago, 1885, a member of the American Medical Association, Mississippi State Medical Association, Mississippi State Board of Health, Tri-State Medical Association; vice-president International Association of Railway Surgeons, 1899-1890; died suddenly at his home in Friar Point, Miss., May 26.

John B. Burdett, M.D. College of Physicians, New York, 1856, for several years president of the Hudson County (N. J.) Medical Society and once president of the Hudson County Pathological Society, died at his home in Jersey City, May 21, from Bright's disease, after an illness of three years, aged 69.

Andrew Louden Chapman, M.D. St. Louis Medical College, 1857, died from heart disease, May 15, at his home in Kansas City, Mo., after a long illness, aged 77. He was at one time the editor and publisher of the *New Medical Era and Sanitarium*. He retired from active practice in 1882.

Eliphalet L. Patee, M.D. Starling Medical College, Columbus, Ohio, 1852, surgeon during the Civil War; surgeon-general of Kansas, 1892-1894, member of the Association of Military Surgeons of the United States, died recently at his home in Manhattan, Kan.

Philip H. Keyser, M.D. Chicago Homeopathic Medical College, 1893; Colorado School of Medicine, Boulder, 1902, a member of the American Medical Association, was found dead at his home in Boulder, May 24, aged 31. Autopsy revealed no cause.

William O. Davies, M.D. captain and assistant surgeon U. S. V., a graduate of the University of Pennsylvania, died at his home in Philadelphia, May 26, after a long illness contracted during his service in the Philippine Islands, aged 36.

Dwight Scott Chamberlain, M.D. New York University, 1862, surgeon during the Civil War, but since 1868 engaged in the law and banking business, died at his home in Lyons, N. Y., May 11, from typhoid fever, after a long illness, aged 64.

Hiram Henry Bingham, M.D. College of Homeopathic Medicine and Surgery of the University of Minnesota, 1896, of Herman, Minn., died in Minneapolis, May 8, from tuberculosis of the intestines, after an illness of two years, aged 28.

Charles F. Hamlin, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1892, a member of the American Medical Association, died at his home in Medway, Mass., May 16, from pneumonia, after an illness of two weeks, aged 34.

Albert N. Robert, M.D. Bellevue Hospital Medical College, New York, 1897, died suddenly from heart disease on the train while returning from his old home in Holyoke, Mass., to his home in Volcano, Cal., May 5, aged 29.

Gustave Boucher, M.D. Royal University of Naples, Italy, 1864, of South Brooklyn, N. Y., died in the Columbus Hospital, Manhattan, May 21, from locomotor ataxia, after an illness of two years, aged 57.

George Osgood Hildreth, M.D. Transylvania University, Lexington, Ky., 1835, the oldest practitioner of Marietta, Ohio, died at his home in that place, May 3, after an illness of four months, aged 90.

W. M. Willingham, M.D. Atlanta (Ga.) Medical College, 1874, died suddenly, May 12, near his home in Crawford, Ga. He had represented Oglethorpe County for several years in the legislature.

Bernard C. Nunez de Villavicencio, M.D. University of Pennsylvania, Philadelphia, 1865, formerly of Galveston, Texas, died at his home in New Orleans, May 21, after a brief illness, aged 64.

Mark T. Loope, M.D. Baltimore Medical College, 1893, surgeon of the Northern Pacific Railway, at Hope, Idaho, died in a hospital at Spokane, Wash., May 22, after a brief illness, aged 46.

John Van Harlingen, M.D. College of Physicians and Surgeons, New York, 1869, died at his home in Brooklyn, N. Y., May 17, from heart disease, after an illness of four months, aged 57.

Henry Klemm, M.D. St. Louis College of Physicians and Surgeons, 1882, died at his home in St. Louis, May 24, after an illness of three months, following an attack of influenza, aged 61.

Nicholas Pfeifer, M.D. Penn Medical University, Philadelphia, 1863, surgeon during the Civil War, died at his home in Lindenhurst, Long Island, N. Y., May 24, after a long illness, aged 83.

Max J. Reinhold, M.D. Hahnemann Medical College, Philadelphia, 1879, died from hemorrhage of the stomach at his home in Williamsport, Pa., after a long illness, May 12, aged 47.

Thomas H. Mathers, M.D. Medical College of Ohio, Cincinnati, 1883, of Lillovet, B. C., died from septicemia following frozen feet, at New Westminster, B.C., April 16, aged 45.

Samuel S. Scott, M.D. Medical College of Ohio, Cincinnati, 1854, a surgeon in the Confederate service during the Civil War, died at his home in Erlanger, Ky., May 22, aged 77.

Waller Overton Bullock, M.D. Bellevue Hospital Medical College, 1869, died at his home in Lexington, Ky., May 18, from paralysis, after an invalidism of four years, aged 61.

Joseph B. Cutts, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1842, an early settler of Polo, Ill., died at the home of his son in St. Louis, May 18, aged 83.

Thomas B. Ennor, M.D. State University of Iowa, Iowa City, 1888, of Potosi, Wis., died at Phoenix, Ariz., April 27, from tuberculosis, after an illness of one year, aged 40.

Arthur A. Blondin, M.D. Northwest Medical College, St. Joseph, Mo., 1892, of Alturas, Cal., died at a hospital in San Francisco, April 28, from heart disease, aged 62.

Henry D. Belden, M.D. University of Vermont, Burlington, 1877, a veteran of the Civil War, died from locomotor ataxia at his home in St. Albans, Vt., May 21, aged 57.

John R. Van Horn, M.D. Georgia School of Eclectic Medicine and Surgery, Atlanta, 1894, died at his home in Clay City, Ind., May 23, after an illness of six weeks, aged 42.

John K. Ruffin, M.D. University of Pennsylvania, Philadelphia, 1857, who had been in feeble health for some time, died suddenly at his home in Wilson, N. C., May 23

William R. Irons, M.D. Jefferson Medical College, Philadelphia, 1890, died at his home in Allegheny, Pa., from pneumonia, May 21, after an illness of four days, aged 42

Asa E. Hoskinson, M.D. Starling Medical College, Columbus, Ohio, 1883, died at his home in Columbus, May 19, from pneumonia, after an illness of two weeks, aged 45.

James I. Lamar, M.D. Medical College of Georgia, Augusta, 1851, died at his home in Deatsville, Ala., May 11, from pneumonia, after an illness of six weeks, aged 73.

John Moffett, M.D. Medical College of Ohio, 1849, several times president of the Rush County Medical Society, died at his home in Rushville, Ind., May 1, aged 81.

Charles Cochran, M.D. Willoughby (Ohio) University, 1843, for many years a resident at Toledo, died, May 25, at the home of his daughter in Los Gatos, Cal., aged 86.

John Nelson McCune, M.D. Cleveland Medical College, 1878, died at his home in McKeesport, Pa., May 17, from dropsy, after an illness of four months, aged 52.

James M. Park, M.D. Eclectic Medical Institute, Cincinnati, 1871, of Little Rock, Ark., died suddenly while driving near Scott's Crossing, Ark., May 15, aged 51.

Joseph N. B. Latimer, M.D. College of Physicians and Surgeons, Baltimore, 1879, died at his home near T. B., Prince George's County, Md., May 18, aged 48

Tyson Smith, M.D. Homeopathic Hospital College, Cleveland, 1881, formerly of Newaygo, Mich., died at the Michigan State Hospital, Kalamazoo, May 11, aged 55

Ephraim M. Fine, M.D. Medical College of Ohio, Cincinnati, 1872, died at his home in Veedersburg, Ind., May 17, from paralysis, after a brief illness, aged 59

Joseph T. Moreland, M.D. Chattanooga (Tenn.) Medical College, 1901, of Atlanta, Ga., died at a sanitarium in that city, May 22, after a short illness, aged 56

James E. Hyslup, M.D. University of Maryland, Baltimore, 1900, died at his home in Keller, Va., May 18, from pneumonia, after an illness of six days, aged 27

William L. Funderburg, M.D. Southern Medical College, Atlanta, Ga., 1883, committed suicide, by taking morphin at his home in Gadsden, Ala., May 12

Alvin B. Rice, M.D. Bellevue Hospital Medical College, New York, 1867, died suddenly from heart disease, at his home in Jamestown, N. Y., May 7, aged 61.

A. M. Gontner, M.D. Jefferson Medical College, 1878, of York, Pa., died at the York Hospital, May 17, from septicemia, due to an abscess of the foot, aged 47.

Carl Steiger, M.D. University of Munich, Germany, 1887, died at his home in Monroe, Wis., May 7, from toxemia, after an illness of four days, aged 42

Clifford J. Hickman, M.D. Eclectic Medical Institute, Cincinnati, 1889, died at his home in South Bend, Ind., May 8, after an illness of one week, aged 35

Edgar T. Schmidt, M.D. Jefferson Medical College, Philadelphia, 1876, died suddenly in his office in St. Paul, Minn., from heart disease, May 17, aged 48

Robert M. Enders, M.D. Tulane University, New Orleans, 1869, captain and assistant surgeon, U. S. V., died in Manila, P. I., May 26, from nephritis

James T. Warnock, M.D. Jefferson Medical College, Philadelphia, 1858, died suddenly from heart disease, May 9, at his home in Atlanta, Ga., aged 68

Raymond W. Shattuck, M.D. College of Physicians and Surgeons, New York, 1897, school inspector, died at his home in New York, April 27, aged 29.

John J. Healy, M.D. University of Pennsylvania, Philadelphia, 1872, died suddenly from heart disease at his home in Philadelphia, May 7, aged 53.

Robert B. McCants, M.D. Southern Medical College, Atlanta, Ga., 1882, died at his home in Demopolis, Ala., May 28, after an illness of two days, aged 45.

Andrew J. Sauer, M.D. Baltimore Medical College, 1894, died at his home in Baltimore, May 20, from typhoid fever, after an illness of 33 days, aged 30.

Silas E. Farnsworth, M.D. University of Vermont, Burlington, 1867, died at his home in Minneapolis, May 21, from chronic nephritis, aged 65.

William L. Kirkpatrick, M.D. Medical College of the State of South Carolina, Charleston, 1850, died at his home in Anniston, Ala., May 3, aged 76.

John F. Cronin, M.D. Medical College of Georgia, Augusta, 1890, of Augusta and New York City, died from tuberculosis at Daytona, Fla., May 23

E. P. Stearns, M.D. Eclectic Medical Institute, Cincinnati, 1858, assistant surgeon in the Civil War, died recently at his home in Newton, Kan.

Ralph Morden, M.D. New York Homeopathic Medical College, 1875, died at his home in Circleville, Ohio, from Bright's disease, May 12, aged 50

William G. Mott, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878, died at his home in Basco, Ill., from smallpox, May 5, aged 60.

Robert L. Browning, M.D. Eclectic Medical Institute, Cincinnati, 1882, died suddenly from apoplexy at his home in Judsonia, Ark., May 6.

Edward M. Kanouse, M.D. Hahnemann Medical College, Chicago, 1880, of Wausau, Wis., died at Three Rivers, Wis., May 25, aged 60.

James F. Rawlings, M.D. Medical College of Ohio, Cincinnati, 1891, died from brain disease at his home in Eldorado, Ill., May 13, aged 34.

Joseph A. Schaeffer, M.D. University of Wooster, Cleveland, 1887, of Ashtabula, Ohio, died in the Cleveland State Hospital, April 30.

Adolph O. Schoeninger, M.D. College of Physicians and Surgeons, Baltimore, 1902, died, May 4, at his home in Newark, N. J., aged 24.

E. W. Dean, M.D. Cleveland Homeopathic Medical College, died from consumption at Colorado Springs, Colo., the first week in May.

Charles T. Hudson, M.D. Tulane University, New Orleans, 1882, died at his home in Yazoo City, Miss., May 21, after a short illness.

Robert M. Cochran, M.D. Medical College of Virginia, Richmond, 1865, died, May 8, at his home in Martin's Station, Ala., aged 62.

John A. Bitting, M.D. Jefferson Medical College, Philadelphia, 1874, died suddenly at his home in Sherman, Texas, May 14, aged 50.

John A. Robinson, M.D. Jefferson Medical College, Philadelphia, 1868, died suddenly at his home in Due West, S. C., May 25.

Frederick E. Baxter, M.D. Bennett Medical College, Chicago, 1883, died at his home in Petersburg, Neb., April 30, from cancer

Samuel H. Thompson, M.D. University of Tennessee, Nashville, 1892, of Arlington, Texas, died, May 20, at Albany, Texas.

Benjamin R. Mosher, M.D. American Medical College, St. Louis, 1891, died at his home in Kinsley, Kan., May 2, aged 73.

John I. Dyer, M.D. National Medical College, Washington, D. C., 1847, died at his home in Washington, May 9, aged 76.

James F. Richards, M.D. College of Physicians and Surgeons, New York, 1859, died recently at his home in Andover, Mass.

Alphonso S. Wilson, M.D. University of Pennsylvania, Philadelphia, 1892, died at his home in Wilkesbarre, May 27.

Abraham Standlee, M.D. American Medical College, Cincinnati, 1857, died at his home in Santa Anna, Texas, May 2.

George W. Noble, M.D. Eclectic Medical Institute, Cincinnati, 1854, died at his home in Edon, Ohio, May 4, aged 80.

Frederick A. Krill, M.D. Homeopathic Hospital College, Cleveland, 1882, died recently at San Luis Obispo, Cal.

Edmund B. Myers, M.D., Pennsylvania, died suddenly at his home in York, Pa., from apoplexy, May 13, aged 73.

Henry M. Beer, M.D. Cleveland Medical College, 1868, died at his home in Valparaiso, Ind., May 26, aged 65

J. H. Bryant, M.D. College of Medicine and Surgery, Philadelphia, 1849, died at Waterloo, Iowa, April 27.

B. Frank Klugh, M.D. of Florin, Pa., was injured in a railway accident, May 13, and died, May 16, aged 61.

J. F. Couch, M.D., a pioneer of Upshur County, Texas, died at his home in Simpsonville, May 7, aged 85.

Thomas H. Rye, M.D. University of Nashville, 1859, died at his home in Turbine, Tenn., May 26, aged 74.

Charles H. Blair, M.D. Bennett Medical College, Chicago, 1895, died at Beloit, Wis., May 17, aged 46.

Houston D. Shrader, M.D., Washington, D. C., died at Sibley Memorial Hospital, May 21, aged 52.

Isaiah Bowers, M.D., died from dropsy, April 28, at his home in Plymouth, Ind., aged 70.

James D. Donnelly, M.D. died at his home in Mountain City, Tenn., May 21, aged 75.

B. A. Tinsley, M.D., died at his home in Lawrenceburg, Tenn., May 11.

Book Notices.

A Text-Book of Diseases of the Eye. A Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. de Schweinitz, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, etc. Fourth Edition, Revised, Enlarged, and Entirely Reset. With 280 Text-Illustrations and 6 Chromo-lithographic Plates. Cloth. Pp. 773. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1903.

De Schweinitz's well-known work on diseases of the eye appears in the fourth edition with numerous changes and additions bringing it well up to date. Much new matter has been added and certain chapters, such as those on refractions, movements of the eyeballs and others, have been considerably rewritten. The work will retain the favor which it has received from the profession.

Therapeutics of Dry Hot Air. By Clarence Edward Skinner, M.D., LL.D., New Haven, Conn., Professor of Thermotherapy in the New York School of Physical Therapeutics. Cloth. Pp. 200. Price, $2.00. New York: A. L. Chatterton & Co.

The subject of this work is one that is likely to interest the practitioner more in the future than it has in the past, for the method advocated seems to have advantages and to have acquired at least a standing in therapeutics. The book gives the best side of the treatment, not, however, without mentioning its limitations. The criticism of the book that we should make is first of all that it does not with sufficient completeness and definiteness describe the mechanism of the apparatus. The illustrations given convey a general idea of its appearance and to a certain extent of its mode of working, but on looking over the work we have been unable to find anything as to the possibilities of its utilization in private practice at the bedside in the absence of gas jets, even indeed if it is practicable where they are available.

Anatomy and Histology of the Mouth and Teeth. By I. Norman Broomell, D.D.S., Professor of Dental Anatomy, Dental Histology, and Prosthetic Technics in the Pennsylvania College of Dental Surgery, Philadelphia. Second Edition, Revised and Enlarged, with 337 Illustrations. Cloth. Pp. 500. Price, $4.50 net. Philadelphia: P. Blakiston's Son & Co. 1902.

This is a text-book for dental students, and is thoroughly up to date. The illustrations include microphotographs from actual specimens as well as photographs of dissections. The author enters into a general description of the mouth and surrounding tissues. The occlusion of the teeth receives considerable attention, although that in itself is of minor importance, since the etiology of occlusion is entirely neglected, the manner and arrangement of the teeth in the line of evolution and atavism being an essential point. About one hundred and fifty pages are devoted almost entirely to the anatomy of the teeth. The histology of the structures of the mouth are entered into at considerable length. This work would be of more value if the first part had been devoted to the evolution of the pulps and the teeth. The evolution of the face, jaws and teeth should be well fixed in the mind of the student before he undertakes the study of the present condition of man, as nearly all diseases which the dentist is called on to treat are the result of evolution. The work as a whole is a commendable one. In one or two instances, the author has failed to give credit for illustrations. This, however, was no doubt an oversight. The work is finely produced with clear large type, and is well indexed.

A System of Physiologic Therapeutics. A Practical Exposition of the Methods, Other Than Drug Giving, Useful in the Prevention of Disease and in the Treatment of the Sick. Edited by Solomon Solis-Cohen, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College. Volume V. Prophylaxis—Personal Hygiene—Civic Hygiene—Care of the Sick. By Joseph McFarland, M.D., Henry Leffmann, M.D., Albert Abrams, A.M., M.D., and W. Wayne Babcock, M.D. Illustrated. Cloth. Pp. 539. Price, $27.50 per set. Philadelphia: P. Blakiston's Son & Co. 1903.

Part 1, by Drs. McFarland and Babcock, discusses the origin and prevention of disease, considering the intrinsic factors which tend to increase or decrease the tendency to disease, such as age, race, heredity, etc. The extrinsic causes are similarly treated under the heads of physical, toxic and sociologic causes, in which a great deal of space is given, profitably, to the different forms of animal and vegetable parasites. Part 2, by Dr. Leffmann, treats of civic hygiene, including chapters on hospitals for contagious diseases, the control of venereal disease, the regulation of water, milk and food supply, the disposal of waste material and the disposal of the dead by burial and cremation. Part 3, by Dr. Abrams, includes such important topics as the hygiene of dwellings; the hygiene of travel; personal hygiene; the hygiene of special periods, beginning with infancy; the hygiene of the diatheses as scrofula, rachitis, scorbutus, etc. The last two chapters are devoted to the care of the sick room and the patient, including a chapter on special nursing. The book includes many helpful suggestions which should be in the possession of every active practitioner. This volume keeps up the reputation of this series in the treatment of subjects in a practical manner.

Association News.

New Members.

New members for the month of May, 1903:

ALABAMA.

Williamson, J. L., Tuscaloosa.
Faulk, W. M., Tuscaloosa.
Camp, E. T., Gadsden.

Connecticut Report.—Dr. C. A. Lindsley, secretary of the State Board of Health, reports that the examining committee of the Connecticut Medical Society, at three different sessions during the year 1902, at New Haven, gave written examinations in 10 subjects, with 100 questions, and required a percentage of 75. The total number examined was 76, of whom 66 passed and 10 failed. In the absence of the percentages usually given in these columns, we give below a summary:

No.	Sch. of Pract.	College.	Found Qual.	Not Qual.
1	R.	Medical College of Alabama..........	..	1
16	R.	Yale University	16	.
5	R.	Baltimore Medical College..........	3	2
2	R.	Johns Hopkins	2	.
3	R.	Tufts Medical College..............	2	1
1	R.	Harvard University	1	.
1	R.	Dartmouth Medical College..........	1	.
1	R.	University of Minnesota............	1	.
1	R.	University of New York............	1	.
1	R.	University of Louisville............	1	.
3	R.	University of Pennsylvania..........	3	.
5	R.	University of Vermont..............	5	.
1	R.	University of the South............	..	1
6	R.	Bellevue Hosp. Med. Coll., New York..	6	.
11	R.	College of Phys. and Surgs., New York.	11	.
1	R.	College of Phys. and Surgs., Chicago..	1	.
1	R.	College of Medicine, Syracuse.........	1	.
1	R.	Cornell University	1	.
2	R.	Long Island College of Medicine......	1	1
2	R.	Starling Medical College............	..	2
3	R.	Medico-Chirurgical, Pennsylvania	2	1
2	R.	Woman's Medical College, Pennsylvania	2	.
3	R.	Jefferson Medical College, Philadelphia	3	.
1	R.	Gross Medical College..............	1	.
1	R.	McGill University	1	.

He further reports that the committee of the Connecticut Homeopathic Medical Society likewise held three different sessions in the year 1902, at Hartford, with the same number of subjects and questions and percentage required, at which the number examined was 6; passed 5, and failed 1, as follows:

No.	Sch. of Pract.	College.	Found Qual.	Not Qual.
1	R.	Trinity Medical College, Toronto......	..	1
2	H.	Boston University School of Medicine.	1	1
1	H.	New York Homeopathic College.......	1	.
3	H.	Hahnemann Med. Coll., Philadelphia..	3	.

The committee of the Connecticut Eclectic Medical Association made no examinations during the year.

Medical Organization.

Reorganization.

We quote the following from the *Medical Fortnightly:* "It is almost the rule that every community which is large enough to have a medical society, has two, such is the perversity of human nature and so difficult is it for us to agree among ourselves. The fact that there are more than enough local medical societies ready and willing to undertake the responsibility of being made the local gateway to the American Medical Association is one of the most troublesome problems in the way of reorganization. In St. Louis there was no question as to which society would be recognized, the St. Louis Medical Society was so easily the most important and the only society which could be seriously considered; other communities are less fortunate, and considerable feeling is being engendered in the endeavor to decide which of the aspirants shall be selected. That all will be happily settled eventually goes without saying, and there can be no question the results of the reorganization will demonstrate the wisdom of its having been undertaken. To hasten this happy time it is necessary that the members of the various county societies show a generous disposition during the present period; in undertaking to represent the American Medical Association locally a responsibility rests on each society to conform to the requirements of the Association. To let a matter of sex or petty personalities cause the rejection of physicians, who are eligible for membership in the National Association in all points except such local membership, should be sufficient to discredit any society with the state and National organizations. A broad and generous interpretation of the code and an elimination of all considerations which have no definite bearing on the ethical or moral standing of a physician in his community should characterize the attitude of all county societies toward those who desire membership with us; lacking this the days of troubles of reorganization will be long continued.

Harrison County (Iowa) Medical Society.

Physicians of Harrison County, Iowa, met in Logan, May 21, and organized a county medical society, with the following officers: President, Dr. Irving C. Wood, Logan; vice-presidents, Drs. R. V. Witter, Woodbine, and Thomas Macfarlane, Mondamin; secretary, Dr. J. H. Gasson, Missouri Valley, and treasurer, Dr. Joseph Knowles, Logan.

Thayer County (Neb.) Medical Society.

Physicians of Thayer County met at Hebron, April 14, and organized a county medical society, with the following officers: Dr. Joseph V. Hinchman, Hebron, president; Dr. George A. Birdsall, Alexandria, vice-president; Dr. Joseph H. Boyes, Hebron, secretary and treasurer; Drs. Cyrus M. Easton, Hebron, Adam Herney, Deshler, and W. T. Reynolds, Hebron, censors, and Dr. Charles C. Snowden, Davenport, delegate to the state society.

Livingston County (Ill.) Medical Society.

At the annual meeting held in Pontiac, May 14, it was voted that the society affiliate with the Illinois State Medical Society. The following officers were elected: Dr. Thaddeus O. Bannister, Odell, president; Dr. John J. Stites, Pontiac, vice-president; Dr. John Ross, Pontiac, secretary-treasurer; Drs. James W. Mitchell, Pontiac, George T. Carson, Chatsworth, and Emmet E. McCoy, Flanagan, censors, and Dr. John Ross, Pontiac, delegate to the state society.

Bremer County (Iowa) Medical Society.

This society, organized in October last at Tripoli, Iowa, with Dr. Herman C. Jungblut, Tripoli, president, and Dr. Bert C. Dunkelberg, Tripoli, secretary-treasurer, held its third meeting at Waverly, May 27, and adopted the constitution and by-laws proposed by the American Medical Association for county societies. After the meeting a banquet was given in honor of Dr. Oscar Burbank, Waverly, who celebrated his eighty-third birthday the day previous, and who has been in active practice for 55 years.

Wisconsin in Line.

At the meeting of the Wisconsin State Medical Society, held in Milwaukee, June 3 to 5, the constitution and by-laws recommended by the American Medical Association was adopted unanimously, a committee of ten was appointed to act as a council for the coming year and till the state is divided into regular councilor districts and councilors elected. Several county societies have been organized in Wisconsin during the past few months, and the work of organization will now be taken up systematically.

Columbiana County (Ohio) Medical Society.

This society was organized at East Liverpool, May 19, and adopted the constitution and by-laws proposed by the American Medical Association for county societies. The following officers were elected: Dr. William N. Bailey, East Liverpool, president; Dr. Arthur B. Holland, Wellsville, vice-president; Dr. William E. Morris, Lisbon, secretary-treasurer; Dr. Wilbert A. Hobbs, East Liverpool, delegate to the state society, and Dr. James T. Elliott, East Liverpool, alternate, and Drs. William S. McFarland, Wellsville, Arthur C. Yengling, Salem, and William M. Calhoun, East Liverpool, censors.

Societies.

COMING MEETINGS.

Minnesota State Medical Society, St. Paul, June 17.
Medical Association of Montana, Helena, June 17-18.
Medical Society of New Jersey, Asbury Park, June 23-25.

American Medico-Psychological Association.—At the annual meeting in Washington, D. C., May 13, Dr. Alonzo B. Richardson, Washington, was elected president.

American Association of Pathologists and Bacteriologists.—At the meeting in Washington, D. C., May 13, Dr. Eugene Hodenpyl, New York City, was elected president.

Kennebec County (Maine) Medical Association.—At the annual meeting held in Augusta, May 20, Dr. Luther G. Bunker, Waterville, was elected president, and Dr. Wellington Johnson, Augusta, secretary-treasurer.

Thurston County (Wash.) Medical Society.—At the annual meeting, May 25, in Olympia, Dr. George W. Ingham was elected president; Dr. John W. Mowell, secretary, and Dr. W. L. Bridgford, treasurer, all of Olympia.

Utah County (Utah) Medical Society.—At the annual meeting held May 6, Dr. J. Franklin Noyes, American Fork, was elected president; Dr. J. M. Henry, Payson, vice-president; and Dr. David Westwood, Provo, secretary and treasurer.

Arizona Medical Association.—At the annual meeting held in Phoenix, May 27 and 28, Dr. Logan D. Dameron, Phoenix, was elected president, and Dr. John W. Ross, Phoenix, secretary. Tucson was selected as the place of meeting for 1904.

American Neurological Association.—At the annual meeting held in Washington, May 13, Dr. Frank R. Fry, St. Louis, was elected president; Dr. Hugh T. Patrick, Chicago, first vice-president, and Dr. Graeme M. Hammond, New York, secretary and treasurer.

American Laryngological Association.—At the annual meeting in Washington, May 13, Dr. Jacob H. Hartman was elected president, and Dr. James E. Newcomb, New York City, secretary and treasurer. Atlantic City was decided on as the next meeting place.

Tolland County (Conn.) Medical Association.—At the one hundred and eleventh annual meeting held in Hartford, April 23, Dr. Edwin T. Davis, Ellington, was elected president; Dr. William C. Haven, Coventry, vice-president; and Dr. Ernest O. Winship, Rockville, clerk and treasurer.

Southern Medical College Association.—At the annual meeting held in New Orleans, May 5, Dr. Christopher Tompkins, Richmond, Va., was elected president; Dr. George C. Savage, Nashville, Tenn., secretary-treasurer, and Birmingham, Ala., was selected for the meeting-place in 1904.

College of Physicians and Surgeons (Chicago) Alumni Association.—At the annual meeting held in Chicago, May 25, Dr. Charles C. O. Byrne, Chicago, was elected president; Dr. C. A. Stevens, Texarkana, Texas, vice-president, and Dr. James Moreau Brown, Chicago, secretary-treasurer.

American Dermatological Association.—At the meeting in Washington, May 13, Dr. Joseph Zeisler, Chicago, was elected president; Dr. Milton B. Hartzell, Philadelphia, vice-president, and Dr. Charles J. White, Boston, secretary and treasurer. The next meeting will be held in Niagara Falls, N. Y.

Galva District (Ill.) Medical Society.—At the annual meeting held in Galva, May 7, Kewanee was selected as the place for the 1904 meeting. Dr. Harry W. Waterous, Galva, was elected president; Dr. Francis O. Lowe, Kewanee, vice-president, and Dr. H. Nelson Heflin, Kewanee, secretary-treasurer.

American Association of Genito-Urinary Surgeons.—At the annual meeting held in Washington, D. C., May 12 and 13, Dr. Edwin C. Burnett, St. Louis, was elected president; Dr. F. Tilden Brown, New York City, vice-president, and Dr. John Vanderpoel, New York City, secretary and treasurer.

Physicians' Club of Chicago.—The annual meeting was held June 1, at which the following officers were elected: Secretary, Dr. Henry F. Lewis; directors (for two years), Drs. Joseph Zeisler, A. M. Corwin, and Charles P. Small; (holdover), Drs. A. C. Cotton, J. Clarence Webster and John M. Dodson.

Hardeman County (Tenn.) Medical Society.—Dr. M. M. Smith, Cedar Chapel, was elected president; Dr. H. M. Milstead, Crainsville, vice-president, and Dr. Robert W. Tate, Bolivar, secretary-treasurer, at the annual meeting held in Bolivar. Whiteville was selected as the next place of meeting, October 13.

Oklahoma Medical Society.—The eleventh annual meeting was held in Guthrie, May 12. Dr. Abraham L. Blesh, Guthrie, was elected president; Dr. Aarcha K. West, Oklahoma City, vice-president; and Dr. Eugene O. Barker, Guthrie, secretary and treasurer. The next meeting will be held in Oklahoma City, November 11.

American Ophthalmological Association.—At the annual meeting in Washington, May 14, Dr. Charles S. Bull, New York, was elected president; Dr. Arthur Matthewson, Brooklyn, vice-president; Dr. Jonathan S. Prout, Brooklyn, corresponding secretary, and Dr. Samuel B. St. John, Hartford, Conn., recording secretary and treasurer.

American Medical Editors' Association.—At the annual meeting held in New Orleans, May 5, the following officers were elected: Dr. Charles E. De M. Sajous, Philadelphia, president; Drs. Charles Chassaignac, New Orleans, and Otho F. Ball, St. Louis, vice-presidents, and Dr. J. McDonald, Jr., New York City, secretary-treasurer.

Ohio State Pediatric Society.—This society, at its annual meeting held in Dayton, June 2, elected the following officers: President, Dr. Edwin W. Mitchell, Cincinnati; vice-presidents, Drs. Daniel G. Reilly, Dayton, and William W. Pennell, Fredericktown, and secretary-treasurer, Dr. William Clark, Cleveland. During this meeting almost fifty new members were enrolled.

American Orthopedic Association.—At the seventeenth annual meeting held in Washington, May 12, 13 and 14, the following officers were elected: Dr. Reginald H. Sayre, New York City, president; Drs. Joel E. Goldthwaite, Boston, and Gwilym G. Davis, Philadelphia, vice-presidents; Dr. John Ridlon, Chicago, secretary, and Dr. Elliott G. Brackett, Boston, treasurer.

Association of American Physicians.—At the annual meeting in Washington, D. C., May 14, Dr. William T. Councilman, Boston, was elected president; Dr. Edward D. Trudeau, Saranac Lake, N. Y., vice-president; Dr. Solomon Solis-Cohen, Philadelphia, recorder; Dr. Henry Hun, Albany, N. Y., secretary, and Dr. J. P. Crozer Griffith, Philadelphia, treasurer. The next meeting will be held in Washington.

Decatur (Ill.) Medical Society for Macon County.—At the annual meeting held May 26, the following officers were elected: President, Dr. Silas E. McClelland, Decatur; vice-president, Dr. Charles M. Wood, Maroa, and secretary-treasurer, Dr. Lynn M. Barnes, Decatur. The society adopted a new constitution and by-laws which followed very closely those recommended by the American Medical Association.

American Climatological Association.—At the twentieth annual meeting held in Washington, D. C., May 12, 13 and 14, the following officers were elected: Dr. James C. Wilson, Philadelphia, president; Drs. Thomas Darlington, Jr., New York City, and Thomas D. Coleman, Augusta, Ga., vice-presidents, and Dr. Guy Hinsdale, Philadelphia, secretary. The next meeting will be held in Philadelphia, June 2 to 4, 1904.

American Pediatric Society.—At the fifteenth annual meeting held in Washington, D. C., May 12, 13 and 14, the following officers were elected: President, Dr. Augustus Caille, New York City; vice-presidents, Drs. Allen M. Barnes, Toronto, Ont., and Edwin E. Graham, Philadelphia; secretary, Dr. Samuel S. Adams, Washington, D. C.; treasurer, Dr. J. Park West, Bellaire, Ohio, and recorder and editor, Dr. Walter L. Carr, New York City.

Maryland Public Health Association.—At the meeting in Annapolis, June 4 and 5, the subjects discussed were vaccination, disinfectants, consumption, typhoid and malarial fevers, water supply of Baltimore and Annapolis, and health as a state investment. The following were elected officers: President, Dr. Thomas B. Owings, Ellicott City; vice-president, Dr. Frank H. Thompson, Annapolis; secretary, Dr. John S. Fulton, Baltimore, and treasurer, Dr. W. Royal Stokes, Baltimore.

City and County Medical Society (Portland and Multnomah County, Oregon.)—At the annual meeting in Portland, May 22, the following officers were elected: President, Dr. Robert L. Gillespie; vice-president, Dr. R. C. Coffey; treasurer, Dr. Albert E. Mackay; secretary, Dr. Alexander D. Mackenzie; councilors, Drs. James F. Bell, James K. Locke and Joseph A. Pettit; delegates to state society, Drs. Andrew C. Smith, Edward P. Geary, William Jones, and Simeon E. Josephi, all of Portland.

Utah State Medical Society.—The ninth annual meeting was held in Salt Lake City, May 12 to 14. Ogden was selected as the meeting place for 1904, and the following officers were elected: Dr. George W. Baker, Ogden, president; Drs. Frederick Clift, Heber City, and Emerson F. Root, Salt Lake City, vice-presidents; Dr. Walter S. Ellerbeck, Salt Lake City, secretary; Dr. James N. Harrison, Salt Lake City, treasurer, and Dr. Samuel C. Baldwin, Salt Lake City, delegate to the American Medical Association.

American Medical Temperance Association.—At the annual meeting held in New Orleans, May 8, the following officers were re-elected: Dr. Nathan Smith Davis, Chicago, honorary president; Dr. Winfield S. Hall, Chicago, president; Drs. Henry D. Didama, Syracuse, N. Y., T. A. McNicholl, New York City, and Henry O. Marcy, Boston, vice-presidents; Dr. Thomas D. Crothers, Hartford, Conn., secretary; Dr. Charles E. Stewart, Battle Creek, Mich., corresponding secretary, and Dr. George W. Webster, Chicago, treasurer.

American Gastro-Enterological Association.—At the sixth annual meeting held in Washington, May 14, Prof. C. A. Ewald of Berlin was the guest of honor, and a banquet was given him by the association. The following officers were elected: Dr. Samuel J. Meltzer, New York, president; Drs. Fenton B. Turck, Chicago, and William G. Morgan, Washington, D. C., vice-presidents; Dr. Charles D. Aaron, Detroit, secretary-treasurer, and Drs. A. L. Benedict, Buffalo, Max Einhorn, New York City, and Edward Quintard, New York City, councilors.

Medical Society of the State of California.—The thirty-third annual meeting was held in Santa Barbara, April 21 to 23. The legislative body has taken up the constitution and by-laws suggested by the American Medical Association for state societies; has made slight changes necessary to adopt it to local condition, and will present it to the society for action at the next meeting. The following officers were elected: President, Dr. H. Bert Ellis, Los Angeles; vice-presidents, Drs. William H. Flint, Santa Barbara and George A. Hare, Fresno; secretary (permanent) Dr. George H. Evans, San Francisco; assistant secretary, H. P. Hill, San Francisco; board of examiners, Drs. Dudley Tait, San Francisco, Lewis S. Thorpe, Los Angeles, Daniel E. Osborne, St. Helena, Walter S. Thorne, San Francisco, and Samuel H. Buteau, Oakland; alternates on board of examiners, Drs. Clark J. Burnham, San Francisco, Albert W. Kirk, San Francisco, and Francis M. Pottenger, Los Angeles; board of trustees, Drs. Curtis G. Kenyon, Philip M. Jones, Andrew W. Morton and Julius Rosenstirn, San Francisco, George A. Hare, Fresno, Thomas Ross, Sacramento, J. Gordon Baird, Riverside, Charles W. Nutting, Etna Mills, Frank L. Adams, Oakland, and Fitch C. E. Mattison, Pasadena. The society will meet in Paso Robles, April 19 to 21, 1904.

AMERICAN SURGICAL ASSOCIATION.

Meeting held in Washington, May 12 to 14, 1903.

The President, Dr. Maurice H. Richardson, in the Chair.

(Continued from page 1595.)

Mikulicz on Gastrointestinal Surgery.

Prof. John von Mikulicz-Radecki, Breslau, Germany, read a paper on the second day entitled "Some Contributions to the Surgery of the Gastrointestinal Tract," in which he divided the subject into the following topics: 1. Cardiospasm and its treatment. 2. Peptic ulcer of the jejunum. 3. The operative treatment of severe forms of invagination of the intestine. 4. Operation on malignant growths of the large intestine.

He discussed each one at some length. In reference to the first topic, in view of the insufficiency of all therapeutic measures for relief, he advised the following operation:

The stomach is exposed by laparotomy and in the anterior wall is made an incision long enough to allow the entire left hand to pass into the stomach. Under the guidance of the fingers, which are pushed forward toward the cardiac end, an instrument resembling a glove stretcher is introduced into the cardiac orifice. Dilatation is gradually effected to such an extent that the blades of the instrument are about 7 cm. apart. Thus is caused a blunt dilatation of the cardia similar to the dilatation of the sphincter ani in case of anal fissure. Then the wounds in the stomach and in the parietal walls are closed.

As to peptic ulcer of the jejunum, the Professor stated that we are pretty certain about its etiology; it can be explained only by the prolonged presence of gastric juice which reaches the jejunum without having been normally diluted and neutralized by bile and by the pancreatic secretions. He does not believe that surgeons are any longer entitled to perform anterior gastroenterostomy, at least for benign affections of the stomach, but considers that the most rational method is the pyloroplastic operation.

Mr. B. G. A. Moynihan, Leeds, England, read a paper on "The Surgery of the Simple Diseases of the Stomach," in which he stated that the great majority of such cases susceptible to successful treatment by surgical measures are due to ulceration or to its complications and results.

Papers on the Therapeutic Value of the X-Rays in Surgery.

Dr. Arthur Dean Bevan, Chicago, read a paper entitled "The Therapeutic Value of the X-Ray."

Drs. Wm. L. Rodman and G. E. Pfahler read a paper entitled "The Value of the X-Ray in Superficial Epitheliomata and Tuberculosis," with the following conclusions:

1. The length of time required for the cure of epitheliomata is longer than by surgical or caustic treatment, while the cosmetic results are better. The dangers are proportionate to the urgency of the treatment as indicated by the degree of malignancy. It should only be recommended in cases that are inoperable either because of the extent of the growth or its location.

2. It is probably the best means at our command for the treatment of superficial tuberculosis and gives better cosmetic results.

3. It should follow all operations for malignant disease or tuberculosis with the twofold object of stimulating the healing process and of preventing a recurrence. In some cases it may be of advantage to give a short course of treatment before operation to destroy the outlying portions of the growth and make such operation of a less formidable nature.

Dr. William B. Coley, New York, read a paper entitled "Further Observations on the Influence of the Roentgen Ray on Sarcoma," in which he described 36 cases. He felt that, in regard to the relative merits of the toxins and *x* rays in inoperable sarcoma, the time had been too short and experience too limited thus far to definitely decide this question. He did not believe that the *x*-ray method should be employed in operable cases of sarcoma, with the possible exception of carcinoma of the extremities, in which operation would necessitate amputation. In such cases he recommended a brief course of the combined *x*-ray and toxin treatment.

Dr. Alex. B. Johnson, New York, read a paper entitled "Some Experiences in the Treatment of Inoperable Malignant Growths by the X-Ray," in which he reported ten cases, nine of carcinoma and one of sarcoma; eight died under treatment and two are still alive and have apparently improved, one of them being the case of sarcoma. He described the technic.

Hernia.

Dr. William B. Coley, New York, read a paper entitled "Results of 1,000 Operations for the Radical Cure of Inguinal and Femoral Hernia Performed Between 1891 and 1902." Out of the 1,003 cases which the author had operated on between August, 1891, and December, 1902, there were 937 cases of inguinal hernia, 756 of which occurred in males and 181 in females, and 66 cases of femoral hernia, all males. In the 66 cases of femoral hernia there was no mortality and the primary union was obtained in all but one case, which formed the only recurrence, the balance having remained well from six months to eleven years. The Bassini method for femoral hernia was employed in 16 cases, and the purse-string suture (with kangaroo tendon) in 50 cases. Out of the 181 operations on the female for inguinal hernia there was no recurrence and no relapse, the method employed being practically Bassini's method for the male. There was no mortality in the 1,003 cases. In children operation should seldom be advised under 4 years, the reasons being that many of the cases at this age are cured by a truss, but after that age in which a truss has been tried and failed, or cases in which the presence of reducible hydrocele prevents a truss from holding the rupture operation is advised. In all adult cases under the age of 50 years operation is advised unless there are strong contraindications. Between the ages of 50 and 70 years operation is advised in patients in good health in cases in which the rupture is held with difficulty by a truss. Six hundred and fifty of these cases were found well from 1 to 11 years, 708 cases were found well from 6 months to 11 years, and 467 from 2 years to 11 years. A careful résumé of the literature on the subject and a comparison of the results obtained by other operators was given.

Dr. N. P. Dandridge, Cincinnati, reported a case of gangrene of 15 inches of cecum and ileum after an operation for appendicitis, with relief of artificial anus after repeated operations.

Operations in Presence of Albumin, Etc.

Dr. John C. Munro, Boston, read a paper on the third day entitled "The Significance of Albumin and Casts in Surgical Patients," in which he stated that while he believed that there was no doubt that there was danger in operating on a patient whose kidneys are incapable of sufficient elimination and where there are secondary organic changes, because a patient exhibits a small amount of albumin, hyaline and fine granular casts, with renal cells, the conclusion should not be hastily reached that he is not a fit subject for operation; on the other hand, the presence of any of these symptoms should be sufficient to cause a thorough investigation. He reported a series of 500 cases showing albumin and casts in the urine, not including those, however, that showed renal degeneration, glycosuria, genitourinary diseases, burns, erysipelas or similar diseases, most of whom were subjected to ether anesthesia, and in none of them was it noticed that any renal damage was inflicted. Out of the series of 500 cases 63 died, 8 from shock, 2 after operation for general peritonitis, 5 from pneumonia, 3 from tuberculosis, 19 from sepsis or severe peritonitis, 4 from senility, and, in addition, there were deaths from embolism, malignant disease, cardiac disease, skull fractures and pancreatitis, where the rôle of the urinary organs must have been insignificant. Of the 4 cases in which death was ascribed to senility, one with cellulitis of the arm had 0.25 per cent. of albumin and casts, one with intestinal cancer had profuse diarrhea, one had a strangulated hernia and the fourth died one month after fracture of the femur, showing only the slightest possible trace of albumin with hyaline and granular casts.

Digital Compression to Cure Aneurism.

Dr. Francis J. Shepherd, Montreal, Canada, read a paper entitled "The Treatment of Aneurism of the External Iliac Artery by Digital Compression, with Report of a Case," in which he referred to the great dangers of surgical interference with the tumor, making amputation of the extremity preferable in many cases to trying to remove the aneurism. He gave a careful résumé of the literature on the subject. The advantages of digital compression are that no apparatus is necessary, the finger being the sole means by which the artery is controlled above the aneurism. This, of course, requires a number of assistants, and does not usually require to be kept up more than 24 hours, in the case reported the pulsation ceasing at the end of 12 hours. This case occurred in a man 43 years of age, who had strained himself by lifting a heavy weight, and some months afterward a swelling appeared in the left groin, which pulsated, was at first soft and painless but gradually became harder and seemed to grow upward into the abdomen. The patient objected to operation, and it was decided to put him on palliative treatment until the session opened, so that relays of students could be secured. He was put on Tuffnell's treatment, and leeches applied over the tumor, iodid of potassium being given internally and very little fluid. At the end of 12 hours pulsation had entirely ceased, the pain having been severe after the first four or five hours until the end of twelve hours, being controlled by hypodermic injections of morphin. After 12 hours the patient had no excessive pain, but compression was continued in a moderate degree for 12 hours more, when the leg was wrapped in cotton wool and carefully bandaged, he being kept in bed for a couple of weeks more, and six months after the operation, although the tumor could be easily felt, there was no pulsation, and it was very hard.

Strangulated Hernia.

Dr. Leonard Freeman, Denver, read a paper entitled "Strangulated Left Duodenal Hernia, in which the Sac Contained the Entire Small Intestine, the Cecum and a Portion of the Colon," in which he referred to the fact that the abdominal viscera and peritoneum are subject to various malformations and malpositions, sometimes acquired and often congenital, and unless the surgeon be familiar with these unusual phenomena his diagnostic ability will be curtailed, by confusing conditions for which he can find no adequate explanation. The peritoneal fossæ may be responsible for the most remarkable forms of hernia and this is especially true of the duodenal fossæ. He carefully reviewed the anatomic formation in this region and reported the case described in the title.

Operations for Goiter.

Dr. B. Farquhar Curtis, New York, read a paper entitled "Thyroidectomy and Sympathectomy for Exophthalmic Goiter," in which he referred to the fact that the surgical treatment of this condition has excited much interest of late owing to the fact that medical treatment failed in many cases, although he believed, if the disease had not progressed too far and the patient's circumstances were such as to permit systematic treatment for a sufficient length of time, rest, hygienic measures and proper medication will generally produce a cure, or at least hold the symptoms in check, but there are many cases amenable to surgical treatment that can not be cured by medicine. However, this treatment is not unattended by dangers, especially acute exacerbations of the symptoms known as thyroidism, which is just as liable, however, to be produced by operation in any other part of the body.

In conclusion, he stated that exophthalmic goiter could be cured by both thyroidectomy and sympathectomy, a perfect result being secured in about 60 per cent. of the cases of thyroidectomy, and an immediately good result appears to be the rule in sympathectomy. Sufficient time has not elapsed to judge of the permanence of the cure, but the immediate results are far superior to those of thyroidectomy. The relative mortality of the two would seem to favor sympathectomy (Kocher 4 deaths in 59 cases of thyroidectomy and ligation only; Jonnesco no deaths in 14 cases of bilateral sympathectomy), although in his own cases the result is the opposite. He believed that local anesthesia should be employed, and sympathectomy should be performed only on one side at a time, a sufficient time being allowed to elapse for the patient to recover from the effects of the first operation.

Operations on the Prostate.

Dr. Willy Meyer, New York, read a paper entitled "Prostatectomy and Galvano-Caustic Prostatotomy (Bottini's Operation); Their Present Status in the Radical Treatment of the Hypertrophied Prostate Gland," which he summed up as follows:

1. The operations making a direct attack on the enlarged prostate gland are preferable to those aiming to exert an indirect influence.
2. We have two useful operative procedures for the direct treatment of the enlarged prostate, i. e., prostatectomy and galvanocaustic prostatotomy (Bottini's operation).
3. In selecting the method indicated in the given case, we must individualize and be guided by anatomic, pathologic and social conditions.
4. Prostatectomy is, of course, the most radical and most surgical procedure; it should be the operation of choice whenever promising success.
5. Perineal prostatectomy offers advantages over the suprapubic method, since it enables the operator to do the operation under the direct guidance of his eyes.
6. Debilitated patients who seem unfit subjects for the more radical operation should not be relegated to catheter life, nor should prostatectomy be performed in order "to let them down easy"; they should be advised to have Bottini's operation done.
7. Surgeons should familiarize themselves with both methods in order to be in a position to do justice to their patients.
8. It is the duty of those refusing to do Bottini's operation under any circumstances to nevertheless advise patients who ask for more radical relief, to have Bottini's operation done, if the operation with the knife seems contraindicated.
9. Further, carefully compiled statistics as to the late results of both operative procedures, preferably in the hands of one man, are desirable in that they will increase our knowledge with reference to the proper selection of the proper method in the individual case.

Diffuse Gonococcus Infection of the Entire Upper Extremity.

Dr. Charles A. Powers, Denver, reported a case of this. His patient was a man of 28 years who developed a very extensive phlegmon in the neighborhood of the right elbow joint with concomitant swelling and edema of the entire limb from the pectoral region and shoulder to the ends of the fingers. The gonococcus was recovered from pus liberated by early free incisions, and was also found in a thin serous fluid which escaped at the site of other openings. The course was protracted over many weeks, the patient recovering with stiffened joints. The author emphasized the fact that systemic gonorrheal infection may invade the tissues in wide variety, the gonococcus having been found in the peritoneum, the pleura, the pericardium, myocardium, endocardium, meninges of the brain and spinal cord, periosteum, perichondrium, muscles and tendon sheaths, bursæ, fascia, the skin, the parotid gland, the kidney and the blood current, as well as the joints.

Myositis Ossificans Traumatica.

Dr. J. F. Binnie, Kansas City, Mo., read this paper, calling attention to the fact that bone may be formed in muscle or tendons under several distinct conditions; there may be a process of ossification attacking one muscle after another, myositis ossificans progressica, producing the ossified man of the freak shows. Often repeated slight traumata give rise to bone growths in muscle or tendon, examples of such growths being "riders' bone," "drill bone," "cavalryman's bone," and "fencers' bone," and lastly there is the so-called myositis ossificans traumatica, where a mass of bone forms in a muscle after a single injury. The author reported a case of the latter in a man aged 41 who had received a severe blow on the right forearm two weeks previously while boxing. One week later the tumor was removed, and eight months thereafter there had been no recurrence and no disability. The paper dealt fully with the literature on the subject and the various theories of the origin.

Method of Instruction in Surgical Pathology.

Dr. J. C. Bloodgood, Baltimore, said that clinical instruction in hospital wards and out-patient departments always has certain defects and limitations as a complete method of instruction. He felt that during the time the student spends in the wards many important surgical diseases had not been seen at all, or so rarely that the student did not get a clear conception of the disease, and in addition it is very difficult for the student to follow the patient throughout the progress of the disease and his after condition. In the Johns Hopkins Hospital the instruction of the third-year medical class in the surgical laboratory is divided into two parts: First, the systematic part, in which the instruction is given by pamphlets, museum specimens, microscopic sections and illustrations. Second, the more difficult or routine instruction, which is limited to the fresh material sent to the laboratory from the operating and autopsy rooms. He then described each of these parts in detail.

Officers Elected.

The following officers were elected: President, Dr. N. P. Dandridge, Cincinnati; secretary, Dr. Dudley P. Allen, Cleveland; treasurer, Dr. George R. Fowler, Brooklyn; recorder, Dr. Richard H. Harte, Philadelphia. The next meeting will be held in St. Louis some time in May, 1904.

(*To be continued.*)

DENVER CITY AND COUNTY MEDICAL SOCIETY.

Regular Meeting, held May 5, 1903.

Dr. S. D. Hopkins in the Chair.

The Prognosis of Diseases Incidental to Military Service in the Philippines.

Dr. G. H. Richardson, U. S. A., said that of the 166 cases of insanity reported in the Army in 1901, 120 cases occurred in the Philippine Islands, or 2 of every 1,000 on duty there. In 1900 the numbers sent from the Philippine Islands to the United States was over 200. During part of 1900 and 1901 he was in charge of the detention ward in San Francisco where these cases were sent for diagnosis and observation. It was found that 25 per cent. of all cases were, on their arrival here, in such a mental condition as to permit them to be returned to duty. The sea voyage home and the fact that they were once more on their native soil seemed to cure them. Those who were sent to the Government Insane Asylum in Washington, he is informed, did not remain there for any length of time, with the exception of those in whom a diseased mental condition existed prior to enlistment. The form of insanity was a mild melancholia with suicidal tendencies. The history of nostalgia was always marked. Secondary effects of heat exhaustion produce various neurotic conditions. They are vague and indefinite. Severe headache, general weakness, local dyspeptic symptoms, loss of memory, epileptiform seizures, local palsies, choreiform attacks, failure of vision and other affections of the special senses. In 1901 21 were discharged for cephalgia alone. It is impossible to determine how far these sequelæ are attributable to sun exposure or how far they may depend on some intercurrent disease. He does not think the condition is altogether due to simple sun heat. There must be some special element in the solar spectrum. This class of cases should be sent back at once to the states or some cool climate. In not a few instances, with the most careful treatment, medicinal and climatic, serious permanent diseases of the brain remain, giving rise sometimes to distressing intellectual enfeeblement. Their symptoms are entirely subjective and, like the "railroad spine" to the surgeon and claim agent, by their irregularity and indefiniteness, they give no end of trouble and worry to pension boards

The gastrointestinal trouble forms the majority of cases sent for treatment Dysentery stands at the head of the list. The amebic form is the more chronic, but more amenable to treatment, especially the local use of high injections of quinin The tendency to relapse, however, is constantly hanging over one who has had it once, and what is worse, is liable to develop abscess of the liver The bacillary form never causes abscess of the liver, the acute symptoms, however, are apt to be more severe and death is likely to occur early in the disease.

Sprue is frequently met with in the tropics It may remain latent there and develop for the first time in a temperate climate. It is characterized by alternating periods of exacerbation and quiescence, inflamed eroded tongue, flatulent dyspepsia, pale, copious, loose, frothy fermenting stools, marked emaciation and a tendency to relapse. It is slow in its progress, and unless cured tends to terminate in atrophy of the intestinal mucosa, and sooner or later prove fatal The prognosis depends on the length of time the disease has existed, the age of the patient being bad for cases over 50, and careless, indifferent patients who do not realize the dangers in which they are, and for those cases who can not or will not restrict themselves to a pure milk diet for a considerable length of time Cases of chronic diarrhea should be examined for the malarial parasite Sixteen cases diagnosed as pulmonary tuberculosis showed the presence of malarial parasites Treatment by quinin for a few days proved the infection to be of malarial origin.

Report of a Case of Cerebral Lues

Dr J E Courtney reported the following case T B, white, aged 24, cook. One year before he came under observation he was thrown from a buggy and struck on the left temple, was dazed for ten minutes He denied any knowledge of ever having contracted syphilis, but recalled he had, some five years ago, a small sore on the glans penis, but it disappeared quickly A year later he had some soreness and swelling in the inguinal region, but no suppuration, no eruption He was in good health afterwards and served with the Rough Riders in Cuba He experienced gradual failure of vision in the left eye for nearly a year, which has now been blind for several months, but with little pain until within the last three days. Left eye tender, tension increased, slight ptosis, ball congested, partial detachment of retina Antedating the blindness of the left eye he noticed he could see objects to the left of the left eye, but not to the right—unilateral temporal hemianopsia About six weeks ago he noticed jerking of the face and twitching of the muscles of the left arm, and then he lost consciousness The day preceding this attack he was very sleepy, and for two days after he slept almost continuously day and night No failure of articulation, but speech slow, gait lacking in elasticity, no decided reflex or vasomotor disturbances He was then in the county hospital for five weeks He had a second fit and in delirium jumped out of a second story window on one occasion, and on another escaped and ran a block or two from the hospital under the idea that he was being killed Inunctions of mercury and large doses of iodid of potassium were administered and he improved rapidly and weighs now forty pounds more than when he was ill The interesting question which this case presents is, whether so slight a trauma started into activity the latent infection, and whether an original antisyphilitic course of treatment would have frustrated such late effects.

A New Sterilizer.

Dr George Moleen exhibited a sterilizer which has the advantages over others in the market by being compact, portable and consisting only of three pieces, which includes receptacle for water, a compartment for instruments and dressings, etc. It is especially serviceable in obstetrical practice.

WEST VIRGINIA STATE MEDICAL ASSOCIATION.

Thirty-sixth Annual Meeting, held in Charleston, W. Va, May 26-28, 1903.

The President, Dr H B Stout, Parkersburg, in the Chair.

The president's annual address contained many suggestions of great importance to the moral and material welfare of the association.

Organized Mutual Defense.

The secretary's report showed the association to be in a prosperous condition and that the great strides it has made during the past year were made possible by its partial reorganization at the last meeting The report closed with the recommendation that the association undertake to protect its members in suits of malpractice.

The association acted on this recommendation and adopted the following resolution:

> *Resolved*—That this Association pledges its moral support and will substantially defend any member who shall be sued; and further pledges the services of any and all its members, when called on, to attend any trial and testify in behalf of the member sued.

Reorganization.

The meeting was an especially pleasant and profitable one. A partial reorganization had been effected in 1902, but, under the impression that the profession was not ready for the adoption of the entire Association plan, no provision was made for a House of Delegates, and this made many other changes in the constitution and by-laws necessary. As in other states where similar action was taken, some confusion and dissatisfaction had resulted, although everybody was greatly encouraged by the fact that, in spite of these difficulties, the membership had been almost trebled during the year, and that an increased interest in every phase of professional work was manifest on every hand After a careful consideration and discussion of the situation, it was finally decided to set aside the action of last year and adopt the American Medical Association plan in full This was done by unanimous consent and with much enthusiasm.

Too much credit can not be given to the officers of the association, including councilors, for the ease with which this complete plan of organization was adopted, although they had able assistance from Drs Jepson, Wilson, Sharp and many other leading members. This makes the third state to set aside the partial reorganization of last year and accept the uniform plan proposed by the Association

Officers Elected.

The following officers were elected: President, Dr. T. L. Barber, Charleston; vice presidents, Drs Thomas M. Hood, Clarksburg; E T. W Hall, Freemansburg; Rolla Camden, Parkersburg; secretary, Dr Wm W. Golden, Elkins; treasurer, Dr. V T Churchman, Charleston, councilors, first district, Drs. C. A Wingerter, Wheeling, and J W McDonald, Fairmont; second district, Dr C. S Hoffman, Keyser, and W. H. Proudfoot, Rowelsburg; third district, Dr W W. Tompkins, Charleston, and O O. Cooper, Hinton; fourth district, Drs W. S. Keever, and H B. Stout, Parkersburg, fifth district, Drs. C. R. Enslow and T. W Moore, Huntington, delegates to the American Medical Association, Drs S L Jepson, Wheeling, and W. H. Sharp, Parkersburg Fairmont was chosen as the next place of meeting

---

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

One Hundred and Fifth Annual Meeting, held at Baltimore, April 28 to 30.

Colored Photography.

Prof. R. W. Wood of Johns Hopkins University opened the session by request, with a lecture on colored photography and photography of objects usually invisible, as waves of sound, bullets in motion, etc.

The Last Fifty Years.

Dr. William Travis Howard, the president, delivered his address, which consisted of a review largely of his personal experience, to show that the past fifty years do not contain all or even the chief advances that have been made in medicine. He gave a sketch of Dr. John P. Mettauer of Farmville, Va., son of a French surgeon of the Revolution, under whom he studied and who was a most original and skilful surgeon, far ahead of his day. He was particularly successful in the treatment of hernia, vesico-vaginal fistula, stricture, etc. He eulogized the faculty of Jefferson Medical College of that day. He paid tributes to the work of Gerhard, who was the first in this country to make the distinction between typhoid and typhus fever, and J. K. Mitchell, who was the first to teach the germ origin of malarial fevers. Dr. William Power of Baltimore was, he said, the best teacher he ever knew, and the first to use quinin in full doses for the relief of the paroxysm of malarial fever. He then spoke of the discoveries of the past half century and compared them with those of previous times, and said that no one should allow himself to be engrossed with the present to the exclusion of the past.

The Second Day.

Dr. Robert W. Johnson reported "Twenty-five Recent Operations for Wounds, etc., of Abdominal Viscera." Dr. William H. Pearce read a paper on "Medical Communism," in which he argued that physicians who make important discoveries in medicine should derive pecuniary benefit from them as they do from their books, and illustrated his ideas by a reference to the case of the late Dr. Walter Reed. Dr. Charles O'Donovan discussed the "Water Supply of Baltimore," and urged that the city should buy the watershed. In the afternoon papers were read by Drs. C. F. Davidson, Robert Reuling, John C. Hemmeter, H. Woods, Jr., W. B. Wolf, H. F. Cassidy, F. C. Boyne, J. Friedenwald, L. J. Rosenthal, W. S. Baer, H W. Kennard, T. R. Brown and T. Cooke, Jr.

Poison Law.

At the business session a committee was appointed to confer with a delegation from the Maryland Pharmaceutical Association with a view to urging before the legislature a law prohibiting the sale of poisonous substances by unauthorized persons. A motion to form a woman's auxiliary to assist in raising funds for a new building was referred to the executive committee. A committee was formed to found a "Fund for the Relief of Widows and Orphans of Deceased Members."

Presentations.

A portrait of Dr. Aaron Friedenwald was presented by his son with a eulogy pronounced by Dr. T. S. Latimer.

Dr. Osler presented a crayon portrait of Dr. John Crawford, and oil portraits were also presented of Drs. Edward White and J. R. W. Dunbar.

Election of Officers.

The following officers were elected: Dr. Eugene F. Cordell, Baltimore, president; Drs. Franklin Buchanan Smith, Frederick, and James M. Craighill, Baltimore, vice-presidents; Dr. J. Williams Lord, Baltimore, secretary; Dr. Thomas A. Ashby, Baltimore, treasurer, and Drs. Harry Friedenwald, G. Lane Taneyhill, Samuel Theobald and John D. Blake, all of Baltimore, executive committee.

Tuberculosis.

At the third day's session Dr. H. Barton Jacobs read a paper on "Our Need of a Mountain Sanatorium for Indigent Consumptives," and the subject of tuberculosis and its prevention was discussed by Drs. Welch, Thayer and Fulton. All advocated notification, and Dr. Thayer urged public sanatoria for both incurable and incipient cases and also public lectures throughout the state.

Other Papers.

Dr. C. Hampson Jones and Wm. Royal Stokes exhibited slides of smallpox patients and tissues.

Dr. J. Clement Clark spoke on the "Increase of Insanity."

Other papers were read by Drs. R. P. Smith, E. B. Claybrook, John Turner, W. F. Skillman, Frank Martin, H. H. Young, A. G. Barrett and L. K. Hirshberg.

At the evening session Dr. Simon Flexner delivered the annual oration on "An Aspect of Modern Pathology."

Dr. C. C. Bombaugh read a poem on "Preventive Medicine."

Drs. L. A. Griffith of Upper Marlboro and J. A. Stevens of Oxford were elected to fill vacancies on the board.

Chairmen of Committees.

The following chairmen of committees were appointed: Library, Dr. G. J. Preston; publication, Dr. J. W. Lord; memoirs, E. F. Cordell; ethics, S. Theobald; legislation, William H. Welch; program, H. O. Reik; membership, W. S. Gardner; general sanitation, Jas. Bosley; finance, T. A. Ashby; county medical societies, C. M. Ellis; delegates to American Medical Association, Drs. Wm. H. Welch and William Osler, with Thomas L. Cullen and S. T. Earle, Jr., as alternates. Dr. H. M. Hurd was elected a trustee.

FOURTEENTH INTERNATIONAL MEDICAL CONGRESS.

Held at Madrid, April 23-30, 1903.

(By Cablegram and Letters.)

(Concluded from page 1600.)

Medicine and Classic Paintings.

In the second general session Holländer, Berlin, gave a lantern address with views of about 200 paintings from public and private galleries which had been inspired by medical subjects. He spoke in Spanish, and dwelt particularly on the so-called anatomic paintings in which he claimed that the Dutch school reached its highest eminence.

Section on Medicine: Importance of Routine Medication.

Dr. J. B. Obregon read this paper and emphasized the long history and the logical importance of the counter-irritant method of treatment. Its action, he said, is most manifest in certain cases of acute edema laryngis and bronchiolitis in which prompt vesication immediately turns the tide of the disease. It is also indicated in all forms of internal inflammation in which it can be applied.

Pneumatic Bulbs for Aseptic Hypodermic Injection.

Dr. Pierre Laurent, Bois-Colombes, proposed a method by which the flow of the fluid from bulbs containing medicaments for hypodermic use may be facilitated. He suggests that the excess of space in the bulbs be filled with gas under pressure.

Physiology and Therapeutics of Hypnotics and Narcotics.

Dr. V. Peset y. Cervera read a paper on this subject, in which he said that these agents are to be divided into those that exercise a direct effect on the brain and those that produce sleep indirectly. As has been shown by histologic and chemical methods, cerebral fatigue depends on an actual alteration in the nervous substance. These changes probably interest chiefly the nucleinic acid and are induced by insufficient oxidation or the action of certain leucomains. The direct hypnotics appear to act in the same manner, but more harshly. The indirect hypnotics and hypnotism act on the brain secondarily through the nerves, respiratory and cardiac functions. The theory of the retraction of the processes of the nerve cells does not satisfactorily explain normal or pathologic sleep. The state of the intracranial circulation expresses the successive phases or grades of the action of the pharmacological hypnotics: 1, Active congestion (excitation); 2, relative ischemia (hypnosis); 3, passive congestion (narcosis). As there is no sleep center, the action must be a general chemical one on the brain.

The Protective Role of Human Saliva.

Dr. Miller, Berlin, described the relations of the saliva to dental caries and other infectious diseases of the mouth. He has found that the saliva of man, *per se*, possesses absolutely no antiseptic or protective properties. Sulphocyanid of potassium has no bactericidal action, nor has the buccal mucosa. The saliva does not contain cytases, nor is it hemolytic. The secret of antisepsis of the buccal cavity lies in the buccal flora. They crowd out and eliminate the majority of saprophytes and pathogenic bacteria by simple outgrowth. Phagocytosis plays an important rôle in the diseases of the soft parts. The character of the teeth predetermines to a great extent the occurrence of caries.

Dr. C. E. Nammack, Utica, N. Y., described the six varieties of climate in southern California, which he calls "The American Italy."

The Influence of the Toxins of Diphtheria and of Tetanus on the Blood.

Dr. H. Kucharzewski, Warsaw, detailed the results of laborious experimental research on the effect of subcutaneous doses of the toxins of diphtheria and tetanus, as shown by changes in the corpuscles, the hemoglobin and the specific gravity of the blood. The results, in general, were the same for both. The erythrocytes and the quantity of hemoglobin are diminished by large and medium doses, while the specific gravity is increased. A polynuclear hyperleucocytosis is present which is at its height in the agony, but which declines gradually in the cases which are not fatal (small doses). In cases which are fatal there is a diminution of the lymphocytes and of the eosinophiles; in non-fatal cases the latter are increased. In infectious diseases, examination of the blood may thus give valuable prognostic indications, depending on the relative increase (favorable) or decrease (unfavorable) of the eosinophiles.

Rational Treatment of Tuberculosis.

M. Monier, Liège, is of the opinion that all our mistakes in phthisiotherapy are traceable to the notion that we can attack the bacillus. The only method of treating tuberculosis is to build up the organism by zomotherapy, fresh air and full feeding.

The Soil for Tuberculosis.

One of the most interesting communications was by A. Robin, Paris, in which he presented his views, which have been fully reviewed in The Journal. He claims that the predisposition to tuberculosis is characterized by exaggerated oxidations and demineralization of the organism, evidenced by declining strength and resisting power. Tonics and stimulants aggravate the evil. Treatment should aim to restrict the oxidating processes, to restore the normal proportion of mineral substances and to combat the tubercle bacilli by local medication, such as inhalation of antiseptics or creosote by the rectum, to be eliminated by the bronchi.

Section on Surgery.

The honorary presidents appointed were Ceccherelli, Parma; Villems, Brussels; Le Dentu and Doyen, Paris; Küster, Marburg, and Sonnenburg, Berlin.

Radical Cure of Femoral Hernia.

Dr. O. v. Lassen, Denmark, said that the methods of Salher or of Schwartz, by which a muscular flap of the pectineus was dissected off and attached to the crural canal were inefficient, inasmuch as the muscle tends to atrophy. He prefers to suture the fascia of the pectineus to Poupart's ligament as far as the falciform process, introducing his needle armed with not too fine gut, but a little deeply into the muscle itself, and taking five or six stitches. The method is applicable in nearly all cases. He has seen only 3 recurrences in 45 cases, although 31 were of two to six years' standing. The recurrences were due to exceptional circumstances and therefore excusable.

Surgical Treatment of Cutaneous Tuberculosis.

Dr. H. Morestin, Paris, said that extirpation was the only method of treatment.

In a second communication he described a plastic operation for prominent ears, comprising the excision of the posterior bands and of pieces of cartilage.

In a third communication he reviewed the methods of cheiloplasty, and in a fourth described an esthetic operation suitable for cases of slight inguinal hernia, in which the incision is made in the hairy region over the pubes, horizontally or vertically. It is especially suited to congenital cases, and does not permit of complicated sutures. (Described in The Journal, page 1543.)

Epiploitis After Resection of the Omentum.

Dr. J. Ortiz de la Torre, Madrid, pointed out that the numerous sutures which had to be sunk in the abdomen, in cases of hernia in which the omentum was resected, multiplied the chances of infection. It manifests itself eight to ten days after operation by fever, pain and tenderness. It tends, rather slowly, to the formation of abscesses, which point either to the exterior or to the intestine, and tend to be well walled off from the peritoneum by adhesions. Treatment should be expectant and narcotic until the abscess points. The speaker urged hemostasis in epiploiectomy by some other method than suture.

Surgery of the Stomach.

Dr. Ceccherelli, Parma, reviewed in detail the various maladies of the stomach and posed as a champion of surgical intervention. He asserted that in very many cases operation accomplished its object, not by attacking the primary malady, but simply by permitting the stomach to empty itself more freely. The organ thus gains the repose necessary to recovery. He holds that even the functional disorders, if severe, indicate operation. Cardenal, Barcelona, thinks that the "pyloric triad" demands operation, and all cases of certain neoformation, even without severe symptoms, and all dubious cases with rapid decline of weight and strength. He regards gastroenterostomy as the best palliative measure against hemorrhage and perforation, and sees no reason why cancer of the stomach should not be cured by radical extermination as in other localities. Hartmann, Paris, is rather inclined to restrict gastroenterostomy in favor of resection in intervention on the stomach.

Heat for Tuberculosis.

Dr. S. Clado, Paris, extolled the application of heat to local and accessible foci as a valuable measure in tuberculous infection.

Dr. T. A. Fort, Paris, said that linear internal electrolysis is easy and almost painless. There is little loss of blood and little danger of urinary fever. No permanent sound is necessary. There is immediate relief and no shock. In 50 cases his mortality has been *nil*. It is superior to gastrostomy in case of stricture of the esophagus, on condition that it is permeable.

Dr. W. Nagel, Berlin, described his method of perineal suture after Tait for restoring the perineum.

Areilza and Arregui, Bilboa, described experimental research which showed that interposition of muscle tissue is a frequent cause for the non-healing of fractured bones and of pseudoarthrosis. They distinguish a special form of the latter due to destruction of the vessels and occlusion of the Haversian canals, for which amputation is the only relief. They call this form "pseudoarthrosis eburnea.'

San Martin, Madrid, is convinced that much of the danger of chloroform can be suppressed by avoidance of mouth breathing. He advocates administering the anesthetic through a single nostril.

Iodoform Filling for Bone Cavities.

Silbermark stated that Mosetig has applied 445 fillings in 121 cases with the technic described recently in The Journal, page 1545. In one instance two-thirds of the diaphysis were removed and substituted by this filling with undisturbed healing.

Pneumatic Instruments in Surgery.

L. Mencière, Rheims, exhibited his "revolver osteotome," which resembles a revolver in appearance and is operated by a trigger, the force supplied by liquid carbonic acid gas. The piston can strike 3,000 blows a minute on the pneumatic hammer armed with the osteotome or chisel. He thinks that there is a future for pneumatic instruments of this kind, as they are easy to manage, simple and inexpensive. Any compressed or liquid gas can supply the power.

Section on Obstetrics: Prognosis of Face Presentations.

Dr. W. Nagel, Berlin, combated the general belief that face presentations with chin posterior were of bad prognosis. He said that this position occurred as a very natural and frequent evolution of primary occipital presentation, and almost invariably righted itself by rotation of the chin anteriorly. Narrow pelves may prevent the entrance of the face, as of the head in other forms of presentation, and always indicated early version. Innate dolichocephaly, as contrasted with the acquired forms, is an important factor in face presentations.

Operation for Retroflexio Uteri Mobilis.

Dr. A. Schucking, Pyrmont, fixes the portio vaginalis and the fornix posterior vaginæ by means of two circular ligatures of silver thread, which remain in place four to six weeks. In 18 cases the results were almost always satisfactory. In one case he replaced Schultze's pessary by an injection of paraffin into the anterior fornix.

Treatment of Placenta Previa.

Dr. A. R. Simpson, Edinburgh, said that most cases of placenta previa demanded immediate bipolar version and slow extraction. If diagnosed late in pregnancy and the hemorrhage has not been severe, an expectant method is indicated. In primiparæ especially we should resort to preliminary tamponade of the vagina or hydrostatic dilatation. In marginal implantations the placental lobules may be separated from the inferior uterine segment with the finger, which permits the os to dilate without fresh hemorrhage. The third stage demands the greatest care, with, at time, tamponade of the uterus.

Section on Pharmacy: Effects of Injections of Antidiphtheric, Antitetanic and Antistreptococcus Serum on the Blood.

Dr. H. Kucharzewski, Warsaw, read a paper on the effects of the subcutaneous injection of these various substances into rabbits, and also of normal serum taken from a horse. He found that these various sera produced exactly the same results when injected in various quantities as did corresponding quantities of the normal serum of the horse. Hence, he concluded that the effects were due to the serum, and not to the specific antitoxic content. In detail, small doses are without any effect. Moderate doses produce a slight hyperleucocytosis for two to three days. Massive doses slightly diminish the number of red corpuscles and the hemoglobin; do not affect the specific gravity, but produce a considerable increase of the polynuclear and diminution of the mononuclear leucocytes.

Section on Rhino-Laryngology: Etiology of Ozena.

Dr. W. Freudenthal, New York, said that ozena is an atrophy of all the inner coats of the nose, due chiefly to excessive dryness of the air, complicated by the secondary invasion of a bacillus. The micro-organism can not enter unless the soil has been previously prepared in this fashion. Sinusitises are frequently secondary to the ozena.

Atrophic Coryza.

Dr. E. J. Moure, Bordeaux, discussed in great detail the various forms of atrophy, rhinitis and ozena, and their combinations. As regards treatment, he said that it was sufficient in case of purulent ozena of adults to suppress the inflamed tissue and to employ nasal lavage. Massage with silver nitrate spray is an excellent mode of treatment. Hypertrophied mucosæ tend gradually to disappear, even if cocain and adrenalin do not affect them, and excision is very dangerous. In pseudoatrophic strumous ozena lavage and general constitutional treatment suffice to cure the rhinitis. Complicating sinusitises demand surgical intervention. Finally, in the true atrophic ozena, in young children, one should employ simply systematic lavage, until the patient has attained an age suitable for operative procedure. At this point the nasal cavity is reconstituted by means of interstitial injections of paraffin, which fill out the cavity and prevent the accumulation of foul-smelling, decomposing secretions.

Section on Neurology: Folies Toxiques.

Dr. J. Galiana, Madrid, read a paper on those cases of chronic alcoholism in which mental degeneration entered as a complicating factor. In such cases the manifestations of chronic and of acute alcoholism are noticeably different from the pure types. In some of these cases acute attacks may resemble the suspension of mental functions of epileptics. The disturbances of chronic alcoholism are accentuated The terminal dementia occurs earlier; instead of the motor system, it is the psychical system, as the point of least resistance, which first breaks down. Alcoholism tends to accentuate and develop all previously existent psychical anomalies. In epileptics it multiplies the number of attacks, but is never a cause of the disease *per se*. In hereditary neurotic or degenerative individuals, alcohol tends much more rapidly to induce delirium; a single debauch may thus precipitate a typical delirium in such cases. The speaker then proceeded to a discussion of the syphilitic psychopathics. Secondary syphilis produces psychical aberrations in degenerates, inducing these effects both through the mental anxiety, the anemia, and possibly cellular intoxications. True syphilitic psychoses are perturbations of the order of delirium, of dementia and of the motor functions. The last are of great diagnostic import, and may be either paralytic, convulsive, tremulous or ataxic. He then detailed the various clinical forms of syphilitic motor disturbances, especially pseudo-general paralysis. It is a factor in most cases of true general paresis which occurs notwithstanding early and thorough antisyphilitic treatment and also persists in spite of it.

Resolutions Adopted by the Congress.

In anatomy the importance of topographic representations of the human body being generally recognized, professors of anatomy are asked to co operate to have an extensive exhibit in this line at the next international congress.

In general pathology, an international committee was planned to revise and classify the known bacteria and study those newly discovered. The authorities were also asked to collect data in regard to the prevalence of rhino scleroma in Spain In pharmacy, the necessity of standardization of curative serums and of international unification of hypodermic injections and heroic drugs was recognized by a resolution to this effect. The section on neuropathology unanimously voted an appeal to the lay press to refrain from publishing the details of crimes, as the contagion of criminal impulses among the population is an established fact. Other resolutions were adopted in regard to the suppression of alcoholism and criminal responsibility, recommending for the latter the legislation on the subject in Portugal and the appointment of experts in mental affections to examine all criminals. Among the four resolutions adopted by the section on pediatrics is one that appeals for the revision of the entire chapter of infantile diplegias, while another urges the construction of more sanatoria for children in the country and on the coast. In dermatology, the committee appointed at the last congress to study the unification of optometric scales, was confirmed and ordered to report at the next congress. The section on otology advocated that the autopsy of deaf mutes should be obligatory in public institutions, and that otology should be included in the medical curriculum.

The general sessions adopted a resolution deploring the increasing multiplicity of languages at the international medical congresses and the confusion resulting therefrom, urging the necessity of adopting a common medium.

Impressions at Madrid.

Many members of the congress commented on the comparative absence of saloons in Spain. Very little distilled or even fermented beverages are consumed and the dramshops, even in the large cities, are frequently a long distance apart Folet mentions, in a letter to the *Echo Méd.*, that at a popular and fashionable restaurant he noticed only one person taking a small glass of cognac in the crowded rooms. During the bull fight the cries of men selling "pure water" were heard on every hand. The enthusiasm of the spectators at the horrors of the bull slaughtering was an interesting psychologic study to the visitors.

The meetings of the sections were held in halls opening into each other, so that the proceedings were disturbed by persons passing through to rooms beyond. The confusion in regard to announcements was also great as the thousands of members gathered at one or at most two small wickets clamoring for information of all kinds. Hundreds of the members gave up the attempt and more were to be found in groups in the world-famous picture galleries than in the section meetings.

The visitors were favorably impressed by the standard of medical science in Spain. Also by the cordial welcome they received, although it was somewhat marred by the cupidity of the general public.

A bull fight had been planned as one of the official entertainments, but this plan was abandoned and the members who attended the bull fights had to pay for admission. The fêtes were all remarkably brilliant and interesting. It was curious to note here and there in the scientific meetings some legal light, civil engineer or other non-medical member of the congress.

Therapeutics.

Sciatica.

G. L. Bailey, in *Cincinnati Lancet-Clinic*, recommends, in the treatment of the acute attacks of sciatica, that the patient be placed in a reclining position in a hot-air apparatus with all the body inclosed, except the head. The affected limb should be comfortably bolstered up and temperature gradually raised to 240 F. or 260 F., according to the toleration of the patient. During this process he should be induced to drink freely of cool water, and ice cloths should be applied to the head. The patient should be allowed to remain in this position for one hour, followed by an alcohol rub, and then he should be put to bed with the limb well supported.

This treatment should be followed out daily for five or six days, when the pain will have been relieved sufficiently to allow gentle massage giving firm pressure over the nerve, and at its point of exit from the pelvis. As the pain subsides the massage may be given deeper and harder. The patient will usually find complete relief within two or three weeks. In the chronic cases the treatment is practically the same, except that more vigorous massage may be given. Nerve stretching may be accomplished by deeply grasping the muscles of the thigh while the patient is lying on his face and the nerve forcibly pushed and pulled by the operator. With the patient lying on his back, the thigh flexed on the abdomen with the leg extended serves a similar purpose for stretching. Massage and electricity, both galvanic and faradic, are valuable in restoring the atrophied muscles and the circulation. The patient should be instructed to carry out such exercises at home as will tend to produce a stretching of the sciatic nerve and give exercise to the muscles.

Metcalf recommends the following in the medicinal treatment of sciatica:

℞.	Tinct. aconiti		
	Tinct. colchici sem.		
	Tinct. belladonnæ fol.		
	Tinct. cimicifugæ, āā	ʒii	8

M. Sig.: Six drops every six hours.

The glycerophosphates are valuable in the treatment of the chronic forms as follows:

℞.	Calcii glycerophos.		
	Sodii glycerophos., āā	ʒiss	6
	Ferri glycerophos.	gr. xxx	2

M. Ft. capsulæ No. xxx. Sig.: One after each meal, three times a day; or:

℞.	Calcii glycerophos.	gr. xv	1
	Mag. glycerophos.	gr. xv	1
	Pot. glycerophos. (75 per cent.)	ʒss	2
	Sodii glycerophos. (75 per cent.)	ʒiss	6
	Aq. destil.	ʒviss	25

M. Sig.: Inject thirty to sixty drops into the seat of the pain once daily.

Locally the following may be applied once or twice daily:

℞.	Acidi salicylici	ʒss	2
	Ichthyol		
	Olei hyoscyami comp.		
	Lanolini, āā	ʒiv	15

M. Sig.: Apply locally.

Hay Fever.

According to L. B. Locard, in *Boston Med. and Surg. Jour.*, the treatment of hay fever is either preventive or palliative. With the proper preventive treatment from 60 to 80 per cent. of the cases may be rendered immune, and by the palliative treatment a large majority of the cases may be given complete relief.

The preventive treatment as outlined by the author consists, locally, in correcting deformities and cauterizing the sensitive areas lightly with the galvano-cautery. The constitutional treatment should be started four or five weeks before the usual commencement of the attack. The object of this form of treatment should be to increase the elimination and decrease the production of uric acid, to correct any neurosis present and other abnormalities.

To increase the elimination and decrease uric acid production, alkalies, lithia and sodium salicylate should be given, together with a proper regulation of the diet. Chloretone should be administered as a nerve sedative, giving it just previous to an expected attack. The palliative treatment consists in the use of adrenalin locally, followed by an oily spray. If this does not check the excessive nasal secretion morphin or atropin will usually control it or caffein and suprarenal gland may be given internally.

The patient should wear smoked glasses for the eyes and use adrenalin solution or boric acid and camphor water as an eye wash.

As a local application in the treatment of hay fever Yeo recommends the following:

℞.	Resorcin	gr. iss		09
	Sod. chloridi	gr. iv		25
	Acidi acetici	m. ii		12
	Aquæ q. s. ad	℥i	30	

M. Sig.: Apply locally with a brush or a swab and repeat the application frequently.

Hydrozone may be used as a local application as follows:

℞.	Hydrozone	℥ss	15
	Aq. destil.	℥vi	180

M. Sig.: Apply as a nasal douche four times a day, beginning two weeks before the expected attack. The author also recommends a local application of deodorized cod-liver oil sprayed into the nares every three hours.

Constipation.

The following combinations are recommended by Huchard in *Prog. Medical*, in the treatment of constipation:

℞.	Pulv. glycyrrhizæ		
	Pulv. sennæ, āā	℥ii	60
	Sulphuris		
	Pulv. foeniculi, āā	℥i	30
	Pulv. sacchari	℥vi	180

M. Sig.: One or two teaspoonfuls at a dose; or:

℞.	Sulphuris sublim.		
	Magnesiæ (calcined), āā	gr. lxxv	5

M. Ft. chart. No. x. Sig.: One powder every two or three hours; or:

℞.	Magnesiæ (calcined)	℥iiss	75
	Lactose	℥iss	45

M. Sig.: One teaspoonful in a little water on rising in the morning; or:

℞.	Magnesiæ			
	Sod. benzoatis, āā	gr. xxxvi	2	40
	Pulv. rhei	gr. lxxv	5	
	Pulv. nucis vom.	gr. viiss		50

M. Ft. chart. No. x. Sig.: One powder as necessary to correct the constipation.

Burnett, in *Med. Summary*, recommends the following in the treatment of constipation:

℞.	Sulphuris	℥ss	15
	Pulv. rhei	ʒii	8
	Pot. et sodii tartratis	℥i	30
	Sacchari albi	℥ss	15
	Pulv. cinnamomi	ʒss	2

M. Ft. chart. No. xvi. Sig.: One every two hours in water.

Epilepsy.

The following combination, according to Morrow in *Med. Summary*, is of value in checking epileptiform seizures:

℞.	Potass. bromidi	℥ss	15
	Chloralis hydratis	ʒss	2
	Tinct. hyoscyami	ʒiiss	10
	Ext. cannabis ind. flu.	ʒii	8
	Aquæ q. s. ad	℥iv	120

M. Sig.: One teaspoonful every four hours during the day.

Acute Attacks of Gout.

The treatment of the acute arthritic attacks in gout, according to Wilson in *Applied Ther.*, should consist of rest in bed and elevation of the limb. The following is recommended locally:

℞.	Atropinæ	gr. iii		20
	Morph. hydrochlor.	gr. xv	1	
	Acidi oleici	℥i	30	

M. Ft. linimentum. Sig.: To be painted over the painful joint with a brush and followed by bandaging the joint with absorbent cotton; or:

℞.	Ext. opii........................	gr. xlv	3
	Ext. hyoscyami	ʒss	2
	Adipis	℥i	30

M. Ft. unguentum. Sig.: Apply to the painful joints with cotton wool; or:

℞.	Ichthyol	ʒi	4
	Ung. bellad.	ʒii	8
	Ol. petrolati	ʒiss	6

M. Ft. unguentum. Sig.: Apply locally night and morning; or:

℞.	Pulveris lini	℥iv	120	
	Aq. bullientis q. s.			
	Guaiacol	gtt. xx	1	30
	Glycerini	ʒi	4	

Misce: Mix the glycerin and guaiacol and spread on the flaxseed poultice and place it on the affected joint; or:

℞.	Linimenti belladonnæ	℥iii	90	
	Morph. hydrochloratis	gr. x		65

M. Ft. linimentum. Sig.: One teaspoonful to be mixed with a tablespoonful of hot water and applied on lint under oil silk every four hours.

The following combinations are recommended by *Merck's Archives* as internal medication in the treatment of chronic gout:

℞.	Formin	ʒi	4
	Lithii salicylatis	ʒiss	6
	Aq. menth. pip.	℥iii	90
	Syrupi	℥ii	60

M. Sig.: One tablespoonful in water two or three times a day.

[The formin in the foregoing prescription is a crystalline powder, soluble in water and alcohol. It is identical with urotropin and aminoform and is a uric acid solvent and genitourinary antiseptic.]

The following is also of service in the treatment of chronic gout:

℞.	Lithii brom.	℥i	30
	Sol. potass. citratis	℥iv	120
	Vini colchici rad.	℥i	30
	Syr. tolutani	℥i	30

M. Sig.: One teaspoonful well diluted in water after each meal; or:

℞.	Pot. iodidi	ʒiv	15
	Vini colchici sem.	ʒiv	15
	Tinct. stramonii sem.	ʒii	8
	Tinct. cimicifugæ	ʒvi	24
	Tinct. opii camph. q. s. ad............	℥iii	90

M. Sig.: One teaspoonful three or four times daily.

Medicolegal.

Refusing Examination—Motion for Specimen of Urine.—The Court of Civil Appeals of Texas holds, in Austin & Northwestern Railroad Company vs. Cluck, not only that, in the absence of a statute authorizing it, a court has no power to compel a litigant to submit his or her person to examination by a physician or any one else, but that a refusal to consent to be examined by a committee to be appointed by the court can not be shown on cross-examination before the jury. Having the legal right to refuse to submit to such an examination, the other side, the court holds, have no right to prejudice the party before the jury by showing an exercise of such legal right. Furthermore, the court holds that if it be conceded that the trial court had the power to compel the party who brought this action to recover for personal injuries to furnish a specimen of his urine for examination by physicians to be appointed by the court, before the other side could be heard to complain on appeal, it must be made to appear that their motion seeking to accomplish that result was seasonably made. The end which they had in view (which was an examination of the party's urine by a committee of physicians appointed by the court) would have required time for its accomplishment. The party would have been entitled to a reasonable time, in the due course of Nature, to furnish the urine, and the court would have been entitled to a like time within which to procure competent physicians to make the examination, and the latter would have been entitled to reasonable time within which to make such examination. For aught that appeared in the record, to have granted the motion at the time it was made might have resulted in an unreasonable delay in the trial; wherefore, the court of appeals holds that it was not made to appear that error was committed in overruling a motion to compel the party to furnish a specimen of his urine for such an examination.

Communication of Smallpox by Incompetent Nurse.—The Court of Civil Appeals of Texas holds, in Missouri, Kansas & Texas Railway Company of Texas vs. Freeman, that when the company took charge of one of its employes for the purpose of isolating, nursing and treating him for smallpox—a dangerous and infectious disease—it assumed and owed a duty to the public to employ competent and experienced persons and agents to perform that duty. It took the risk of all consequences of a wrongful execution of that duty, resulting from the incompetency of a nurse or guard so employed by it. It was the duty of the company's surgeon to employ a person as nurse or guard who had sufficient intelligence and discretion to remain isolated, and not leave the camp and go on the public streets, where he would likely come in contact with persons who had not had the disease, without first disinfecting his person and changing his clothes. It was the negligence of the company's surgeon in employing an incompetent nurse or guard that placed the latter in a position where he could, by reason of his negligence and incompetency, communicate the disease to others. And the court thinks that the company is liable where, as in this case, it employs an incompetent servant, and puts him in charge of a pest camp containing persons afflicted with smallpox, to isolate, nurse and guard such persons, and the servant, by reason of his want of discretion and incompetency, negligently leaves the camp and goes on the public streets of the city, and communicates the disease to another. If one to whom the nurse communicated the smallpox knew that the latter was a guard or nurse at a pest camp, but at the time he met him on the street was under the impression that he had disinfected his person and changed his clothes, and would not communicate the disease, then it was for the jury to determine whether such person was guilty of negligence in so coming in contact with such nurse.

Validity of Practice Acts—Who Exempted Practitioners.—The Supreme Court of Washington says, in the case of State on relation of J. W. Smith vs. Board of Dental Examiners, that the wisdom of such regulations, pertaining not only to dentistry, but also to the practice of medicine and surgery, is apparent. It is of the highest importance to the state that suffering and afflicted humanity shall not be subjected to the care and treatment of unlearned and unskilled persons. In its effort to prevent such a misfortune to its people, the state may adopt a standard for the test of fitness to engage in the work of what should be a learned profession. When that standard is adopted, those who assume to do the work of such a profession must prove their fitness by the test of such standard. Otherwise they violate the law, and can not be recognized by the state as practitioners of a lawful profession when they seek to follow it in an unlawful way. And where there was a proviso that the section of an act requiring an examination to practice dentistry should not apply to persons engaged in the practice of dentistry at the time of the passage of the act who were *bona fide* citizens of the state, the court says that it must be held to refer to the practice of dentistry as it was then recognized by law. It thinks that it should presume in this connection that, when the legislature used the words "persons engaged in the practice of dentistry," it did not intend to include in that class persons who had never complied with the existing law entitling them to engage in such vocation, and who had furthermore openly and continuously violated that law. The persons exempted from the examination were those who had complied with the law, for they were the only ones actually practicing dentistry, as that term must be construed in the light of lawful regulations. The subject of an act being to regulate the practice of a given profession, the court holds that the legislature may include in the act the means related to the subject for effecting the object sought.

Probability of Insanity as a Defense to Crime.—The Supreme Court of Iowa says, in the homicide case of State vs. Thiele, that the existence of disease in the brain of a living being is seldom the subject of demonstrated or direct proof. Of necessity, reliance must be placed on outward manifestations, and from these the inference drawn as to the condition of the brain. The conduct and speech of a party are not always the true index of mental capacity or incapacity. Cases of feigned insanity are not infrequent, and about all courts are able to do in most cases is to speak from the evidence as to the probability or improbability of the accused having been insane at the time under investigation. By saying insanity is probable is meant, as understood in common parlance and from the definition of lexicographers, that there is more evidence of insanity than against it, or better reason to believe the accused insane than to suppose him sane. In this case the jury were told, in effect, that, even if it were made to appear probable that the accused was insane, he must be held accountable for his act. And more, that such probability would not alone overcome the presumption of sanity. He must have gone still farther and introduced evidence to overcome this presumption, and then, in addition thereto, satisfy the jury of his insanity by a fair preponderance of the evidence. But the supreme court holds that there was error in this. It says that even if the presumption were to be accorded some probative force rather than treated as a mere rule concerning the burden of proof, it ought not to be offset in this way against the probability of the accused's insanity. Sanity is the normal condition, and the presumption that it exists goes no farther than the assumption, for the purposes of the trial, that the accused is not different in this respect from other men. The law does not undertake to measure the precise amount of evidence which, when undisputed, will rebut this assumption and justify the conclusion that a person is abnormal, save that it must be enough to convince the understanding. But the jury are not to be told that the presumption is of no consequence in weighing evidence, or that it is not to weigh the presumption of the accused's sanity against any measureable amount of evidence of insanity, for an appreciable weight of evidence is required to establish the existence of an abnormal condition of the mind. Not until the evidence indicates that the existence of insanity is probable, that is, is such as to render this conclusion more reasonable than a contrary inference, has the assumption that the party under investigation was in a normal state been overcome.

5 *Reflex Symptom from Biliary Calculus. G. W. Squires.

1. **Mammary Cancer Treated by the X-Ray.**—Morton describes the utility of the *x* ray in cases of mammary cancer and reports a number of cases treated by this method. He uses no shield except for the hair of the head, eyebrows, etc., covering the nipple with a small metallic disc for part of the time. Dermatitis was intentionally carried to the purplish stage, followed by exfoliation and effusion of serum, and in some cases a purulent discharge. In all but one, complete recovery of the skin occurred in from one to four weeks. These areas of dermatitis have often occupied the entire skin area of one breast and axilla. The patients are frequently *x*-rayed from behind the scapula. He thinks this measure is of importance as the deep fasciæ of the muscles of the chest may be affected and the thorax offers but little resistance. The clavicle and ribs may shield infected areas behind the bones. He does not hope for good results unless dermatitis is produced. He has never overstepped the bounds and reached necrosis, but has escaped this only by adhering to the most rigid and exact technic as to time and exposure, distance of tube, force of, radiation, and number of treatments per week. The technic is fifteen minutes, 9 inches, high tube (corresponding to a six to ten inch spark gap), clear view of end of radius and ulnar at two feet, and three times weekly. The question of diagnosis is mentioned. He thinks the margin of error is small. Severe dermatitis should certainly be avoided. What is desired would seem to be to set up a mild leucocytosis with tissue reparation, and if in the case of a mammary and unbroken cancer the skin intervenes, this latter suffers a dermatitis lesion merely to enable the operator to set up a similar but lesser lesion in the deeper tumor area. He has often noticed in cases of primary carcinoma that whenever the patient complains of soreness of the skin, she also remarks that the tumor is unusually sensitive. In superficial or ulcerating carcinoma milder treatment with no dermatitis will suffice. It would not be wise, he thinks, to try to do with the *x* ray what might better be done by the actual or other cautery or by the knife, and the best future for the *x*-ray and phototherapy in general would be extreme conservatism and desistance from the invasion of surgical procedures which offer an alternative of relief or cure to the patient, superior to what the radiation treatment can offer. He holds it as generally admitted that it is advisable to follow up operated cases with radiation to prevent recurrences.

2. **Conjunctivitis.**—Thomson describes the various methods for meeting conjunctivitis according to its type. He thinks there is nothing that will supplant silver, but some of the new germicides seem of value where silver is not well borne. It is imperative in adult cases, and especially in gonorrheal conjunctivitis, to apply medical applications as early as possible. If the gonococcus once has a chance to penetrate the conjunctival tissue thoroughly the eye will probably be lost. In babies the results are not apt to be so serious, but in every case the application of silver should be as early as possible. It is impossible to lay down rules as to the limits of time when the abortive plans of treatment may be used, but he always attempts it when there is any prospect of success. If he sees the case two days after the infection and the swelling and discharge are not at their greatest height, he applies a 3 to 4 per cent. solution of nitrate of silver as thoroughly as possible, and meets the further indications as they arise, using a 2 per cent. solution as a daily application. When using a stronger than 2 per cent. solution it is well to neutralize with salt solution on account of the danger of staining of the cornea. Where silver irritates, as shown by the increased discharge of serum and a tendency to bleed, a 6 per cent. solution of protargol may be used. This is not non-irritating, though less irritating than silver. It is a valuable drug in ophthalmia neonatorum and wherever the conjunctival thickness is not enough to support nitrate of silver applications. It may be dropped in the eye twice daily. In other forms of purulent discharge due to the pneumococcus, Koch-Weeks' bacillus or other pus organisms, protargol in a 6 per cent. solution once daily is a most valuable germicide. It does not stain the tissues like the *nitrates, and it is* good practice to flood the corneal ulcer occurring in the course of a gonorrheal conjunctivitis with a 6 per cent. solution once a day. It does stain the conjunctiva if continually used. Argyrol, 25 per cent., meets the indications of pro

targol and is not irritating. It is less effective when an astringent is required, but as a non-irritating germicide it is ideal. The other indications for treatment in purulent conjunctivitis are best met on old lines, and the use of saturated boric acid solution, ice cloths to the lids, the use of argyrol, or protargol for corneal complications; in some few cases scarification in chemosis and cauterization of the cornea, where the chemosis is not severe, may be valuable means to prevent ulceration. Pure carbolic acid is the best cauterizing agent. When corneal infection appears hot-water applications are to be used for the purpose of stimulating the corneal tissues.

3. **Venesection.**—Ten cases of various conditions in which venesection was used, including pneumonia, eclampsia, asthma, dyspnea, etc., are reported by Andrews. In all the cases but one relief was prompt. The method cured in the sense that it tided over an emergency. He thinks there is possibly much value in this neglected therapeutic operation.

4. **Rhus Diversiloba.**—Schwalbe finds from his study of the cases as reported that there is little evidence of poisoning by diffusion of the toxin through the atmosphere. It must be directly applied and may be carried from one person to another by contact, but the fact that the skin of the face is the most susceptible and that it escapes in those cases where atmospheric contagion has been claimed, indicates that neglected contacts are really the causes of the trouble. Persons perspiring easily are more liable than others. Neutral soap will not clear out the hairs containing the poison; an alkali is required to neutralize it. A 1/10 to ½ per cent. solution of carbonate of potash applied several times a day is sufficient to protect everybody against the bad effects of this interesting plant.

5. **Biliary Calculus.**—Squires reports a case where severe pain and an eruption on the heel was the result of a biliary calculus and was immediately relieved on its removal *per vias naturales.*

10 On Simplicity in the Operation for Laceration of the Cervix Uteri. Louis Kolopinski.
11 Tuberculosis of the Larynx and Aspiration Tuberculosis of the Lungs Following Dermatitis Blastomycetes. Otto T. Freer.

7. **Radiotherapy.**—Park discusses the physical principles underlying radiotherapy, and offers the following conclusions as safely warranted in regard to the therapeutic effects of the *x*-rays and ultra-violet rays: 1. They afford methods of treatment for extremely new growths of limited area and superficial character, which, while not exactly certain, are extremely promising. 2. They not only cause no pain, but tend to relieve pain, both superficial and deep, in a most pleasing and satisfactory way. 3. They are adapted to cases which can hardly be submitted to any other method of treatment, and they afford more hope in delayed and inoperable cases than does any other method of treatment. 4. It will be found that the odor of putrefaction may often be suppressed by their use and the putrefactive process itself checked. 5. Burns and intense dermatitis, so frequently noted when the treatment first came into vogue, may now be almost entirely avoided. 6. More than this, they afford a supplementary method of treatment after operation by which the benefits of the same may be enhanced or enlarged. 7. It is not necessary to intermit such work as the patient may be engaged in in order to carry out the *x*-ray or phototherapeutic method of treatment. He remarks that too much must not be expected, and that what may be accomplished in deep cases is yet unknown. The *x*-rays have, however, been of apparent benefit in relieving pain, even deep seated.

8. **Anal Fissure.**—Lewis has found permanganate of potash applications in "anusol" suppositories night and morning curative in anal fissure. His worst case, in which all other means had failed, was cured by this treatment in ten days.

9. **Suprarenals in Skin Disease.**—Engman and Loth have tried suprarenal with good success in skin disorders dependent on vasomotor disturbance, pruritus, urticaria and lichen urticatus. They find a certain cumulative action on the nervous system that makes them use the drug with caution. It caused in repeated doses, 5 gr. 3 td., tremor of the extremities, aggravated by increased doses. For a child under 4 they give ½ gr. 3 td., gradually increased to 2 gr. Between the ages of 4 and 12, 1 gr., gradually increased to 3 grs. Above 12 the beginning dose may be 2 gr., increasing gradually to 6 gr.

17 *Uterine Fibroma Near the Menopause. George E. Shoemaker.

13. **Fracture of the Neck of the Femur.**—Bissell describes the methods of treatment used in several hospitals in New York City. In St. Vincent's there were few of these cases in the year 1900, and only 41 cases since that time. The method used is a fracture board under the mattress, a Hamilton long side splint and Buck's extension with a weight, usually rather heavy, sufficient to reduce the shortening down to one-half inch or under. The Hamilton splint was removed frequently comparatively early, often at the end of the fourth or fifth week. No plaster dressings have been used during the three years. No deaths are recorded. In Bellevue 241 cases are reported from Jan. 1, 1900, to Jan. 1, 1903. The method employed is the fracture board, Buck's extension and the long Hamilton splint as the usual means. The weights were somewhat less than those at the St. Vincent's. Only in one case was the plaster-of-paris spica used from the beginning of treatment to the end. In a number of other cases, however, the plaster was applied after the Hamilton splint had been removed and shortening reduced as much as possible and no amount of weight seemed to reduce it further. In the New York Hospital there were 34 cases recorded. The usual treatment in almost every case was to apply the Hodgen splint. The fracture boards for the bed and occasionally Buck's extension were used with sand bags and moderately heavy weights applied until shortening was reduced as much as possible. The longest period a patient was kept in bed was sixteen weeks and the shortest six. Fifteen of the 34 cases were discharged as cured, 4 as unimproved, 14 as improved and 1 died from pneumonia occurring within twenty-four hours after admission. In none of the hospitals was any operation performed to unite the fractured surfaces, to remove a detached head or to carry on or assist in any manner the treatment. The largest percentage of cures was in the New York Hospital, which speaks well for the methods there employed. According to the author's experience, bed sores are a common intercurrent trouble in these cases, though this does not seem to be borne out by the histories as recorded in these hospitals. He thinks the difficulty of meeting the indications of perfect coaptation and immobilization of the fractured bone, together with attention to the health and comfort of the patient, can not well be met by the methods that have been employed. Coaptation and immobilization are perhaps, to a certain extent, met by the Hodgen splint, but much more is required, and the use of a hip splint, which would allow the patient to be up and about, and fixation by plaster of paris, are the only alternatives to an open operation down to the seat of the fracture and an accurate securing of the fragments by mechanical means, which would seem to him desirable. He holds that the risk of surgical operations in these cases is not so great as that of the tedious and slow and unsatisfactory treatment without cutting.

14 This article appeared elsewhere See THE JOURNAL of April 18, title 53, p. 1105.

17. Uterine Fibroma.—Shoemaker has operated on a large number of cases near the menopause, several of which he reports He holds the danger of operation in cases of this class, while greater than in simple abdominal sections, is not very great The mortality should not exceed 6 per cent, and it is largely due to complications such as pyosalpinx, recurrent peritonitis or the effects of hemorrhage, all due to delay

21 Etiology and Treatment of Retrodeviations of the Uterus Charles A Robertson
22 Strongyloides Intestinalis in Texas with Report of a Case John T Moore
23 *Streptococci Infections Leonard K Hirshberg

18 Friedreich's Ataxia—Collins describes the typical form of Friedreich's ataxia and notes the types that have been described He gives two cases which he thinks illustrate the fact that the disease conforms to the classic type with some frequency He calls attention to the uniformity of the clinical manifestations and also to some uncommon clinical features, such as preservation of the tendon jerks, pes planus, manus cavus and an uncommon complication, the Menière symptom complex, which occurred in one of the cases reported

19 Congenital Dislocation of the Hip.—Gibney reviews the treatment of congenital hip joint disease, and especially the effects of the Lorenz method He considers stretching of the capsule an element of danger and unnecessary The number of cases in which paralysis of the quadriceps femoris and leg muscles have developed indicates this He offers in conclusion the following few points that seem to him to be paramount

1 Do not rest content in a case of hip lameness in a young child until you have made a thorough examination of the patient and have obtained a full history of the case 2 The diagnosis once established aim to effect a reduction before the sixth or seventh year It is fatal to postpone operation 3 In patients beyond the age limit fortify yourself with a Roentgen ray picture in order to determine the exact position of the head the shape of the same and the relationship which the neck sustains to the shaft. 4 Do not make long attempts at reduction in patients over 10 5 Bear in mind the dangers which Dr Lorenz himself has warned against namely, too extensive laceration of the soft parts, paralysis which may or may not yield to time and treatment, the fracture of the femur or the pelvic bones, rupture of an artery, sometimes the femoral

20 Congenital Dislocation of the Hip.—Davis criticises the Lorenz method, holding that it is unnecessarily severe and has developed dangerous features, and maintains that the comparatively mild and gradual methods of Paci are preferable Forcible traction, he holds, has no place in immediate reduction of congenitally luxated hips, and it is mainly responsible for the traumatisms that occur If we are to avoid them we must adhere more closely to the original teaching of Paci, which consists simply in the application of the circumduction method of reducing traumatic luxations, by which the thigh is flexed on the abdomen followed by downward pressure on the knee with abduction, external rotation and gradual extension The pressure is made on the trochanter posteriorly while the limb is carefully extended Abduction is afterwards maintained to an extent sufficient to prevent the head from escaping from its new position He prefers the fixation of the thigh on the abdomen to fixation at right angles with the body He says that rather than resort to the great force now at times employed, he believes it would be much better to incise and clear a way for the head of the bone

23 Streptococci Infections.—Hirshberg reviews the facts in regard to the various pathogenic streptococci, and holds that there is little warrant, with our present means of differentiating bacterial species, for dividing the streptococcus into eighteen or more species as is done. From the multiplicity of pathologic processes in which the streptococcus is invariably found, it is quite likely that there are distinct species or at least varieties of streptococci involved, but our present means of separating them proves it is open to considerable doubt

24 Backache—From an orthopedic standpoint certain well-defined types of backache present themselves which are divided roughly into two groups by Lovett, those due to causes existing in the spine itself and those due to external causes The first of these are either mechanical or static, due to faulty attitude or the result of injury or inflammation Among the first Lovett mentions faulty spinal attitude, in which the extra strain is borne by certain ligaments not calculated for them, hence pain follows from continuous ligamentous strain, especially when associated with stretched spinal muscles In round shouldered, lax spined young woman pain is not infrequent and is familiar under the name of irritable or neurasthenic spine, and is generally localized in one or two points, is apt to be severe and aggravated by exercise Stiffness comes on after a while, and in old cases the differentiation from Pott's disease and osteoarthritis may be difficult. The condition tends to grow worse with periods of improvement, and the cure lies in the development of the spinal muscles and the acquirement of an erect attitude by gymnastic exercises, at first mild, later increasing in force, following the line of the "setting up drill" of fthe military recruit. The physician must be sure of his diagnosis, for the same treatment is not suitable for Pott's disease. In lateral deviation of the spine, when due to a shorter leg on one side, pain is not uncommon and is often situated in one or the other of the sacroiliac joints, or in the loin or around the scapula. As far as Lovett's experience goes, the pain is on the convex side of the curve rather than on the compressed side. The correction of the shortened leg by a thick sole will in many cases do away with the backache The causes due to injury or trauma include sprains of the back which are often serious, far more so in their symptoms than would be suggested by the anatomic conditions. In some cases it is impossible to make an off hand diagnosis from Pott's disease. Instead of being put to rest like an injured ankle, it is the rule that the parts are kept in action and treatment is, therefore, embarrassed. In chronic or acute sprain absolute rest and fixation are necessary, or their restricted use There is also a persistent backache without obvious cause, of which he has seen two cases The patients were not neurasthenic, they stood well, their muscles were good, and they had suffered no injuries, and in both cases the condition was obstinate. In conclusion he mentions Pott's disease and arthritis deformans and the causes of backache existing outside the spine. Three conditions of the foot are mentioned, such as flatfoot, which is not common in private practice, pronated foot, which is more common, the weight of the body being transmitted diagonally through the arch instead of straight down, and pain and irritability result This is most commonly called flatfoot, but it outnumbers the cases of real flatfoot many times over. Another condition is what is called contracted foot, which is very little known and but imperfectly understood. It is characterized by shortness of the muscles of the back of the calf and their stretching is necessary in the treatment. Backache is a common accompaniment The pain from these three conditions is generally in the small of the back and is aggravated by stooping or standing. It also results from walking The real flatfoot and pronated foot are easily treated by foot plates, and the backache disappears if this is the cause In case of contracted foot, stretching of the calf muscle is necessary, and the under side of the foot must be supported by a pad or a short steel plate The arch of the foot must be correctly supported

25. Cocain Herniotomy.—Lyle describes his method of operating under cocain, insisting on the importance of keeping the patient unaware of what is being done. It consists in blocking off the nerves by injection, careful dissection and practically the Bottini operation with the exception of the treatment of the sac, in which he follows the Macewen method, which, as we know, retains the sac, and pulling it with a purse-string suture or No. 4 catgut through the internal or deep ring, anchors it there by carrying this suture through the abdominal muscles and skin about an inch above the upper extremity of the skin incision, there winding the end of the suture around a small piece of sterile gauze. This leaves an obstruction in the internal ring. The advantages claimed for the method are, that we are saved the danger of general anesthesia to the heart, lungs and kidneys, that we cut no nerves, and therefore do not impair their function, and ligate no vessels; there is no shock, nausea or straining. The patient continues on the full diet and can enjoy a hearty meal immediately after the operation; all cases have healed by primary union. The patient is confined to bed for three weeks, after which time he may be about and return to work.

26. **Aseptic Labor.**—The essentials of aseptic labor are given by Gallant as follows: (*a*) a good-sized hand bag, to be used for this purpose and no other; (*b*) stocked with the necessary drugs; (*c*) steam sterilized gauze, gown and cotton ball sponges (several sets of which must be kept on hand); (*d*) hand brushes, silkworm gut, rubber gloves, and catheter, ready to be boiled in plain water; and (*e*) a set of metallic instruments to be boiled in soda solution when needed. As a time-saving measure these supplies, dressings and instruments should be arranged on a table standing conveniently near the accoucheur's right hand, and the drugs placed in a row on the mantel, to obviate soiling the bag and infecting the operator's hands. The hand cleaning can best be accomplished (without antiseptics) by the liberal application of the tincture of green soap, rubbed thoroughly into the dry hands and arms (two or three coats), working the soap well under the nails and between the fingers; then, when they are thoroughly coated and dry, scrubbing with a stiff brush, in running water, until all traces of soap have been scrubbed away. Before applying the forceps or introducing the hand into the vagina, cut short the hair, soap well, and scrub the vulvoanal region, the thighs and abdomen as carefully as you have the hands. Put on rubber gloves if the hands recently have been in contact with septic wounds or pus from any source.

28. **Sarcoma of the Kidney.**—In the case reported by Richmond, the patient had a swelling which crowded the liver and organs forward and inward. The posterior dulness reached as high as the eighth rib. There was a great loss of strength and flesh. The diagnosis made was that of sarcoma, which, however, was not verified by any exploratory operation. Night sweats were frequent, the patient became very weak; the tumor extended downward as far as the crest of the ileum. The treatment was the *x*-ray for nineteen consecutive days. At the end of that time the temperature had decreased to normal, night sweats were lessened; the tumor had apparently ceased to grow and seemed softer and the patient was generally improved. She was then sent to the hospital, where the treatment was continued, and at the end of nine weeks the growth had entirely disappeared as far as could be determined by bimanual examination. At the present time, April 1, 1903, she seems quite well, though she has not fully regained her powers of endurance. He intends to continue the *x*-ray treatment two or three times weekly for the next few months as a precautionary measure.

29. **Urogenital Tuberculosis.**—Cumston describes two cases illustrating the ascending and descending forms. He holds that the ascending form is generally more favorable than the descending type, because operative treatment is more easily accomplished, and also from the fact that an earlier diagnosis is far easier to make.

30. **Heredity and Tuberculosis.**—Packard and Roos review the literature as to the hereditary transmission of tuberculosis, and claim that it is not only a possible, but an important mode of transmission. They insist on the danger of transmission by heredity and the criminality of marriage of tuberculous patients. Experimental evidence by Friedmann shows that tubercle cultures injected into the vagina directly after sexual intercourse in rabbits produces infection of the ovum, which shows that sperm highly charged with tubercle bacilli may produce the same trouble. The authors also think that the tuberculin reaction is perhaps rather uncertain as a diagnostic method. Negative results are too frequent.

31. **Chronic Pneumonia.**—Palier reports a case which came on with an acute onset followed by very slow recovery lasting for several months. The condition, he thinks, is often mistaken for consumption, and change of climate and exercise advised, which is a mistake.

45 Tobacco Poisoning. A. C. H. Friedmann.

37. **Alcohol in Surgery.**—Gould has studied the use of alcohol in surgery and has found it of very limited utility. It seems to impair convalescence and he would not place it among the means of primary value in the treatment of shock and collapse. It is injurious in cases of cancer, though there are special circumstances in which it may be used with good effect for securing sleep or promoting appetite. In conclusion, he remarks that it may not be the best treatment to absolutely withdraw alcohol from those that have been used to it as the breaking up of a life-long habit may in some instances be injurious.

38. **Surgery in Inebriety.**—The theory under which surgery may be advantageous in inebriety proposed by Rodebaugh is that certain conditions may interfere with what is called the nerve force and reduce the resistance, and he reports a case where operations for hemorrhoids which were a source of irritation leading to nervous waste, for phimosis and for deflected septum were efficient in combating the alcohol and morphin habits.

39. **Hypnotism in Alcoholism.**—Bramwell reports cases where hypnotism has been used in curing the alcoholic habit and dipsomania. The important points of treatment are that the patient must be willing to be cured, and must be susceptible to hypnosis, though deep hypnotism is not requisite for good results. In dipsomania the treatment ought to be begun at the quiescence of an attack and aim at retarding or weakening the next attack. When stimulants are taken continuously the patient should be encouraged to discontinue gradually or at once. The management of the patient before suggestion has taken effect is important. He should always be under the supervision of some trustworthy person who can advise and help him to overcome the temptations. Actual restraint is useless and the moral effect is always bad. The operator must be persevering and not easily discouraged; many persons relapse once or twice during treatment. The distaste for alcohol ought to be suggested as well as the abolition of the craving of it. The patient should look forward

with the idea that he can never be a moderate drinker, that his only alternative is total abstinence or the gutter. Even when the craving disappears quickly the hypnotism should be continued regularly for a month, and if the patient can be observed for six months so much the better. The object of treatment is not only to cure the disease, but to strengthen the will: if the patient can not control himself it is a failure. Bramwell thinks his results are encouraging, but he hopes for still more satisfactory ones.

40. **Hasheesh Insanity.**—The director of the Cairo asylum describes his experience with hasheesh insanity, which seems to be more frequent in that country than elsewhere. There is a close analogy between the condition of certain hasheesh habitués and dipsomania. He notes the following special points: 1. Suicidal intentions are common among alcoholics, rare among hasheesh cases. But we must bear in mind that most of the latter are Mohammedans, among whom suicide is rare. In Egypt hasheesh seems to be a more important factor in the production of insanity than alcohol is in England, and as a cause of crime of equal importance. The use of hasheesh, unlike that of alcohol, is not accompanied with any characteristic anatomic lesions and no physical disorders of note are met. The only exception to this is the staggering gait of hasheesh intoxication and delirium. In general only the physical disorders and lesions met with in idiopathic insanities are encountered.

46 Inflammation of the Pelvic Organs Involving the Vermiform Appendix, with Report of Cases and Exhibition of Specimens. C. M. Fulton.
47 *The Operative Treatment of Hernia. Robert McE. Schauffler.

47. **Hernia.**—The operative treatment of hernia is reviewed by Schauffler, who insists on the importance of radical operation for cure. The mortality is slight and constantly being reduced, and unless there are objections on account of age, either too early or too advanced, or mechanical difficulties, as in very large hernia with danger of increasing intra-abdominal pressure by reduction and special idiosyncrasies to anesthetics, the results are fairly good. The operator should be thoroughly familiar with anatomy. Antisepsis should be rigid and the technic should be dry, with little handling and careful control of trifling hemorrhage. The Bassini operation is the best for inguinal hernia. He, however, calls attention to a few points. Whatever the skin incision, let the incision in the external oblique aponeurosis be a full finger's breadth from Poupart's ligament, so that it may be reflected in a lower as well as an upper flap. Have the suture material absorbable, kangaroo tendon, reindeer tendon or chromicized catgut. Suture the conjoined tendon, which is rather a muscle edge than a tendon, to Poupart's ligament with broad bites of muscle and shallow but firm ones in the ligament, taking care to retract well the lower external oblique flap which is continuous with Poupart's ligament. Do not tie too tight, lest the muscle atrophy. The cure depends on the firm union of the approximated parts, not on any permanent strength of the suture material. The crucial point in the suturing is to have the first suture, or the first two if one is placed above the cord, give snug approximation of the new internal ring to the cord without unduly constricting it. The aponeurosis of external oblique should be overlapped if possible, at least nicely approximated, without the sutures being very tight. This tissue is poorly nourished and easily sloughs. In femoral hernia the greatest difficulty is to distinguish the sac and true hernial contents from the tumor of true peritoneal fat which so often precedes or surrounds it. Never dissect a mass of fat blindly; it may have a little "glue finger" of intestine or bladder as its center. Almost any closure is successful in a femoral hernia, but the position of the femoral vein must always be kept in mind. In umbilical or ventral hernias in small patients, not very fat, the prognosis is good. With large or irreducible hernias in fat people with adhesions and attacks of inflammation or partial strangulation frequent it is much more serious. It is often wise, he says, to circumscribe the mass, including redundant skin, and come down on normal peritoneum just beyond the hernial opening and then reduce as much as possible, working from within, and resect the remainder of the omentum with part of the sac and skin in one mass. In the closure the peritoneum is stitched flat, as in laparotomy, and the abdominal wall closed in layers, taking special care to approximate the recti muscles. Small hernias in the linea alba or lateral walls are easily cured by such closure as is indicated by ordinary surgical common sense. Post-operative ventral hernias are treated along the same lines. In strangulated hernia the condition is more serious. Even apparently successful taxis is attended with considerable mortality. Recent statistics favor resection rather than colostomy. There are many cases of hernia imperfectly controlled by a truss or retained at the cost of much discomfort where operation would be better and the danger of taxis is a very serious one.

48 *Sensations Interpreted as Live Animals in the Stomach. Alfred Stengel.
49 Syphilis of the Lungs Simulating Pulmonary Tuberculosis. Alfred Stengel.
50 Methods of Clinical Examinations, Embodying the Practical Course Given to the Third Year Students of the University of Pennsylvania. C. Y. White.

48. **Live Animals in the Stomach.**—Stengel has investigated the alleged cases of this kind and reports one case where the belief of live animals in the stomach was maintained by the patient. He says, in view of these cases and others like them, he is convinced that the cases of supposed invasion of the stomach by various animals are often instances of gastric disease with misinterpreted sensations. These are not to be treated on the theory that they are pure delusions, as they are, in many cases at least, instances of organic gastric disease which may be relieved by appropriate treatment.

Annals of Ophthalmology, St. Louis.

April.

51 *Report of Cases of Extensive Symblepharon and of Shrunken and Obliterated Cul-de-Sacs, Relieved by Skin Grafting, with Description of the Operation. H. W. Woodruff.
52 *Anomalous Direction of Retinal Vessels on Emerging from and Entering Optic Disc. E. F. Snydacker.

55 Four Eye Injuries with Introduction of Foreign Substances Not Suitable for Removal by Magnet. M. W. Zimmerman.
56 A Case of Acute Glaucoma, with Iritis, Following Cataract Extraction. James Bordley, Jr.

51. **Symblepharon.**—Woodruff's method of treating these cases is by skin grafts. He thoroughly cleanses all the parts and flushes the field with boric acid solution. If pseudopterygium is present, it is first dissected through, the lid thoroughly freed from its attachment to the eyeball and the cul-de-sac made large in all dimensions. Cicatricial bands should be removed entirely. Bleeding is checked by hot water. A plate is now cut from a sheet of block tin, which will snugly fit into the new-formed cul-de-sac. The corners are rounded off and the edges smoothed with the scissors or file. The plate may be cut out in the center to prevent rubbing on the cornea, if necessary. Four holes are made for the sutures, two at the outer and two at the inner angle of the plate, to correspond to the lid margin. A thin layer of skin is removed about one-third wider and more than three times as long as the plate. This is taken from the inner surface of the arm flattened by pressure. The plate and graft are then pushed into the cul-de-sac and sutured to the lid near its margin, tying the ends of the sutures over small rolls of gauze. The lids may be sewed together and dressed with gauze and bandaged in the usual way. The eyes should be bandaged as long as the plate is in place, and absolute quiet maintained. The plate is removed in four days and more freedom allowed the patient. Six cases are reported. He thinks the method is the best up to date. The white surface of the graft may be quite noticeable for awhile and objected to, but the graft can be placed at once where it is wanted, and is held down in the very bottom of the artificial cul-de-sac until it has adhered, and approximation and rest are secured by the plate.

52. **Anomalous Direction of the Retinal Vessels.**—This peculiar anomaly of the retinal vessels described by Snydacker

consists in the superior and inferior temporal veins and arteries, on emerging from the optic nerve, proceeding directly toward the nasal portion of the retina as if that were their destination; afterwards turning towards the temporal portion where they were distributed as usual. He thought this was but a coincidence with the defective sight in his first patient, but he shortly afterwards met with other cases showing the same peculiarities. There was also some congenital deficiency present besides the anomalous vessel exit, and there were also marked errors of refraction, most frequently myopic astigmatism. He finds very little mention in the literature of this condition.

60 *Conditions and Diseases of the Eye Which Make an Enucleation Necessary. A. J. Erwin.

60. **Enucleation of the Eye.**—The conditions requiring enucleation are enumerated by Erwin as follows: 1. A blind eye which menaces a sound one. 2. A nearly blind eye which has set up sympathetic disease should not be removed, and every operator should keep this distinction in mind. 3. Every lacerated eye with a ragged wound in the ciliary region should be removed before it has time to set up sympathetic disease, and also 4, every eye which contains a growing tumor before it involves the orbital tissue. Lastly, he says, eviscerate early in panophthalmitis. These indications are discussed in detail. The second rule is important, that a diseased eye with some sight which has already set up sympathetic disease in the other eye will not save the other eye by its removal, and it is worth while to save what sight it has. Not every ciliary laceration warrants enucleation. A clean rent that has healed promptly without contraction is fairly safe so long as it remains free from irritation, but ragged laceration calls for enucleation before it has had time to cause disease of the other eye. As regards the operation, he thinks a careful study of the conditions present in each case is required. With threatenel sympathetic disease of the other eye, simple enucleation where applicable would be judicious; also, in panophthalmitis simple evisceration would be best and easiest, and enucleation, not evisceration, should be done in all cases of interocular tumor, as they usually involve the sclera. Evisceration should always have preference where there are adhesions of the sclera or capsule unless contraindicated. He reiterates that where there seems to be an immediate danger of sympathetic ophthalmitis simple enucleation or evisceration should be done, but the demand for the best cosmetic effect now requires in all other cases the Lang or Mules operation where possible. The technic of the two operations is described.

66 Report of Two Cases of Laryngeal Paralysis Due to Aortic Aneurism. Hal Foster.
67 Superheated Medicated Air in Diseases of the Ear and Nose. Joseph C. Beck.

61. **Hypertrophic Rhinitis.**—Shurly discusses the etiology of this condition, which he largely attributes to defects of development owing to evolution of the nasal region in the higher races. The upper nasal passages of the Caucasian are only abnormally normal, and this lack of proper structure tends to the production of the condition. Other causes that may occasion it are attacks of measles, diphtheria, scarlet fever, etc., which every child must go through, and still another cause is the artificial mode of living, especially of the well-to-do class. Lastly, he believes that a new etiologic factor will arise in the prevalent consumption of fake foods and nostrums, and consequent abuse of the metabolic functions.

62. **Rhinoplasty.**—The new operation described by Douglas was devised in a case of depressed fracture of the bones, where he found he could not raise them from below, and in which he made an open mask for the face with a sort of bridge running down the course of the nose. Working from within he supported the adhesions and sutured the bones with sutures which were passed out through a common opening in the bridge of the nose and fastened to the bridge of the mask, thus supporting the outlines of the nose in a normal position. The result was good.

63. **Malignant Tumor of the Nasopharynx.**—Quinlan reviews the literature of these growths and finds that there is sufficient evidence to show that aside from the pseudo-malignancy of certain rapidly growing fibromata there is the possibility of true sarcoma and no reason, a priori, to exclude carcinoma from this region. The type usually described corresponds to adenocarcinoma. As regards treatment, he does not give a hopeful opinion. The prognosis of malignant growth in the nasopharynx is very unfavorable. The character of the tissues favors rapid malignancy, and the results have only been very slightly modified for the better. This is largely due, however, to the fact that the condition is not recognized early enough. When patients are in middle life and when symptoms are suspicious, careful examination should be made. Every day of delay makes the prognosis worse and temporizing measures are almost criminal.

64. **Middle-Ear Disease in Tuberculosis.**—Levy concludes his paper with the following summary:

1. Any of the usual aural affections may affect the tuberculous as well as the non-tuberculous. 2. The usual modification of an acute otitis in a tubercular subject is manifested in the course the disease pursues. 3. It is a doubtful question whether the *Bacillus tuberculosis* is present as a distinctly etiologic factor or as an accident. 4. Comparatively few cases of tuberculosis in children and relatively few instances of bone tuberculosis are met with in Colorado. 5. Clinical tuberculous otitis occurs with moderate frequency in Colorado, being secondary to lesions of the respiratory organs. 6. Tuberculous otitis may develop when the general symptoms of tuberculosis have been arrested and the patient's condition is unusually good. 7. Tubercle bacilli may find their way into the middle ear through the Eustachian tube, through the lymph channels of the blood currents. 8. Unusual care must be exercised in the application of the nasal douche in tuberculous patients. 9. The discharge may be arrested, but not permanently, as a rule. 10. It must be exceedingly rare for miliary tuberculosis to develop from an otitis as the focus of infection. 11. Through and through irrigation with tubercle-bacilli destroying agents is of prime importance in the treatment. 12. General and climatic treatment must be conscientiously carried out.

65. **Pin in the Larynx.**—In the case reported a pin was firmly fixed across the larynx and could not be removed by forceps without too extensive laceration of the tissue. Several methods were suggested, but the plan finally adopted was to seize the pin at the center with a hook, then by pressing it double it up. A canula, bent at the proper angle to enter the larynx, was very firmly fixed at right angles to a heavy handle, carrying a lever, to whose upper end was fastened the stiff steel wire that passed through the canula. This wire terminated in a hook at its distal end. The hook at the end of the canula was easily carried around the exposed part of the pin and continuing to hold the instrument in the same position pressure was made on the lever of the handle and the pin bent back and jack-knifed itself so that it was drawn out of the tissue and up into the canula, without the patient knowing anything had been done. The recovery was complete and rapid.

70 Some Points in the Diagnosis and Treatment of Diseases of the Nose and Throat, and Their Relation to General Medicine. Willis S. Anderson.
71 Acute Dilatation of the Stomach. W. M. Harvey.

69. **Blood Pressure in Surgery.**—The following is a summary of the results of Crile's study of the blood pressure in shock:

Surgical shock is an exhaustion of the vasomotor center. Neither the heart muscle, nor the cardio-inhibitory center, nor the cardio-accelerator center, nor the respiratory center are other than secondarily involved Collapse is due to a suspension of the function of the cardiac or of the vasomotor mechanism In shock, therapeutic doses of strychnin are inert, physiologic doses dangerous or fatal. If not fatal, increased exhaustion follows. There is no practical distinction to be made between external stimulation of this center, as in injuries and operation, and internal stimulation by vasomotor stimulants, as by strychnin Each in sufficient amount produces shock, and each, with equal logic, might be used to treat the shock produced by the other Stimulants of the vasomotor center are contraindicated Cardiac stimulants have but a slight range of possible usefulness, and may be injurious In collapse, stimulants may be useful because the centers are not exhausted Saline infusion in shock has a limited field of usefulness. In collapse it may be effective. The blood tolerates but a limited dilution with saline solution Elimination takes place through the channels of absorption Its accumulation in the splanchnic area may be sufficient to fix the diaphragm and the movable ribs, causing death by respiratory failure Saline infusion, in shock, raises, but can not sustain the blood pressure Adrenalin acts on the heart and blood vessels It raises the blood pressure in the normal animal, in every degree of shock; when the medulla is cocainized, and in the decapitated animal It is rapidly oxidized by the solid tissue and by the blood Its effects are fleeting; it should be given continuously By this means the circulation of the decapitated dog was maintained ten and one half hours In excessive dosage there is a marked stimulation of the vagal mechanism The pneumatic rubber suit provides an artificial peripheral resistance without injurious side effects, and gives a control over the blood pressure within a range of from 25 to 60 mm mercury. Physiologic rest, posture, heat, artificial peripheral resistance, guarded use of adrenalin and particularly when there has been considerable hemorrhage normal saline solutions are the most reliable means of combating shock—but prevention is the best cure By combined use of artificial respiration rhythmic pressure on the thorax, and adrenalin injected into the jugular vein animals which were apparently dead as long as fifteen minutes were resuscitated The control of the blood pressure is almost equal to the control of life itself

His paper concludes with a study of the different conditions for blood pressure determination after various operations

75 Oxyuris Vermicularis in the Appendix Ernest A Hill

73 Hyoscin Hydrobromate Ether Anesthesia.—Robertson recommends the use of 1/100 of a grain of hyoscin hydrobromate one half hour before the administration of ether. The patient is calm and dozes off with quiet respiration, the mouth dry, takes ether without struggling and the stage of surgical anesthesia is quickly reached. There is little or no secretion of fluid from the mouth or respiratory tract, no muscular rigidity or cyanosis and a very small quantity of ether is required. There is no vomiting or obstruction to the respiration by secretion of fluid in the air passages The patient regains consciousness rapidly, but is quiet and sleepy for the first twelve hours after the operation There is some dryness of the mouth and thirst He has never seen any dangerous symptoms follow the use of the drug and he thinks that it prevents or lessens many of the disagreeable or dangerous effects of ether

8 Observations on Empyemata in Children P Stanley Blaker.
9 Six Cases of Empyema Oswald F Rowley.

1. The Influence of Wind on Phthisis.—Among the various climatologic elements that effect the progress of phthisis, wind seems to be considered as uncertain. Gordon reviews the opinions of various authors and analyzes the statistics of certain Devonshire parishes which are more or less exposed to the wind, especially the southwest winds and ocean winds. He finds from a careful study of the subject that the direction of the wind exerts a very positive influence on consumption mortality and that these regions exposed to strong, damp winds have the highest ratio of mortality of consumption. He sums up his conclusions in the following:

1. West and southwest winds in Devonshire have a marked influence on phthisis, raising the phthisis death rate among populations exposed to them, and injuring those who have already developed the disease. 2. This bad influence is probably due to the fact that west and southwest winds are the prevalent strong wet winds of the country. 3. It is reasonable to believe that strong, wet winds anywhere may produce similar effects. 4. The bad effects may be possibly explained by the chilling and depressing nature of the winds, and by their tendency to excite bronchial catarrh in those exposed to them.

4. **Traumatism and Tuberculosis.**—Weir reports a case of tuberculosis occurring in a man in the prime of life and in ordinary health, following an injury to the chest. The family history was tuberculous, but the patient had always been well excepting for pneumonia twenty years before. One sister died of phthisis, said to be due to injury to the chest. In his own case there was a clear sequence of injury with apparently succeeding pleurisy followed by pulmonary symptoms, the presence of tubercle bacilli, etc. The patient recovered under pulmonary gymnastic treatment together with the usual medical aids. Weir remarks on the importance of traumatism, suggesting that in our ordinary estimation of the significance of pleurisy we may have the cart before the horse, and pleurisy may not be due to consumption, but consumption to pleurisy, causing adhesions and making a point of lessened resistance for the attack of the tubercle bacillus.

5. **Anthracosis.**—Phthisis was formerly considered to be a regular occupation disease of coal miners, but owing to sanitary improvements in late years this is less the case. While all miners will show a blackening of the lungs, this is by no means an indication of disease. The really formidable dust particles are not those from coal or soot, but the particles from the sandstone strata or dust from other rocks, etc., associated with the coal. The average life of the horse or pony in the pit is fully up to the average standard, and he believes that there may be some protective influence in the coal dust or coal carbon particles inhaled by the miners. He says that in fact the average coal miner often works in a mine under more healthy conditions than those under which he lives at home. He mentions the following facts as worthy of note:

1. Coal dust may remain imbedded under the skin for years without producing any irritation whatever. 2. The death returns from phthisis in a colliery district show a greater proportion of deaths among females than among males. 3. Colliery surgeons almost invariably state that phthisis is not so common in mining as in other districts where they have been in practice. 4. In the majority of phthisis cases which do occur there is a strong family history of phthisis on one or both sides. 5. Phthisis often seems to attack successive families in particular houses.

6. **Physiologic Differences Between the Two Sides of the Chest.**—Squire has investigated 58 persons, 28 males and 30 females, as to the physical signs on the two sides of the chest, all young adults and in general good health. Only in a very few were there signs of disease, and of which the subjects themselves were hardly aware. The general results are summarized by him in the following conclusions:

1. In the majority of healthy persons, but not in all, the physical signs elicited over the upper part of the right lung differ somewhat from those on the corresponding part of the left side.

2. These differences consist in the following: (*a*) The percussion note is slightly less resonant and higher pitched on the right side; (*b*) the breath sounds are louder on the right side, and the expiratory portion of the sound more marked; the character of the sound and the proportion between the length of the inspiratory and expiratory sounds is not modified in health; (*c*) the vocal resonance, especially in men, is more marked on the right side; (*d*) vocal fremitus is more marked on the right side.

3. Of these differences the increase in the vocal fremitus is by far the most constant. Differences in the percussion note are only noted in half the cases examined.

4. The differences, except in percussion, are not so much alterations in the character of the signs as modifications in transmission of the sounds.

5. The modification in the signs are apparently due to the direction and form of the main bronchus, which are not the same in the two lungs. The percussion note modification may possibly be influenced by the thicker covering of the right side of the chest, but is most probably also dependent on the position and size of the bronchus.

10. **Operative Surgery.**—Bennett reviews the record of surgery, which he thinks passes through certain stages with the surgeon: 1. The period of extra-confidence in operative work; 2, a feeling of less aggressiveness; 3, a tendency to confine one's work to certain operations with which the surgeon is most familiar and his practice becomes more eclectic; 4, in fortunate cases the period when operations may be things of the past. He deprecates too much following of operative ideals. In many cases the necessity of complete operation may be wanting. Rules of routine procedure are objected to. The mere safety of the operation sometimes tends to obscure the fact that its results are not altogether advantageous. While the use of exploratory operation has been on the whole advantageous, he thinks there are still some possibilities of its being overdone. He remarks on the position of the surgeon toward the public; the difficulty sometimes of the patients or their friends persisting in demands for operation, and considers the responsibility of surgeons in these cases. He believes in the future that the operative surgeon as we now know him will be a less imposing figure in the medical landscape than he is now, and operations, except in a restricted degree, which he advocates, will be looked on with as little favor as suppuration is regarded at the present time.

11. **The Tongue in Disease.**—Dickinson reviews the various conditions of the tongue in disease, especially those that may be symptomatic. The first stage of disease is what he calls the dotted or stippled tongue, characterized by a trifling excess of epithelium on the papillæ. It may not necessarily mean ill health, it may be an individual peculiarity. It is not usually accompanied with pyrexia. The coated or loaded tongue comes next. This is an exaggeration of the former state, a superabundance of epithelium, by putting too much on or taking too little off. Some degree of febrile action is usually present. The average temperature in his study of 49 cases was 99.1. The method of taking food is often concerned in the production of this type of tongue, but it occurs in a great variety of cases where the patient is out of sorts, though not really ill. Whatever raises the temperature, impairs the appetite and restricts the salivary flow gives rise to this state of affairs. When the coated tongue is dry the indication is more grave. Two varieties are mentioned: the strawberry tongue and the plastered tongue, which is simply the ordinary coated tongue, only more so. A first glance of this gives the alarm of either pneumonia or typhoid fever in the first place, then of acute bronchitis or acute rheumatism. Other acute disorders may be indicated, though less prominently. The average temperature in the 29 cases presenting this tongue was found to be 101.6. This is the most definite in its indications of all the tongues of which we know. Next he mentions the furred or shaggy tongue, which is more characteristic of chronic than of acute cases. Except with the diet this tongue has no special association, though some degree of pyrexia is usually present. He has noticed it in pneumonia, typhoid and acute rheumatism, which generally means a long illness of such a sort as to restrain saliva and inhibit solid food. Succeeding the plastered and furred tongue comes the incrusted, brown and dry tongue with the elongated papillæ separated and caked over with a brittle crust, cracked and fissured, which largely consists of vegetable organisms. It indicates a long exemption from wear and wash, or the absence of mastication, production of saliva, and generally, though not neces-

sarily, of high temperature. This is the tongue of the typhoid state, though not limited to typhoid fever. It is of grave prognosis and calls for liquid nourishment and stimulants. Next he speaks of the denuded tongue, red, smooth and dry, which is usually associated with pyrexia and deficiency of saliva. It represents a later phase of disease than the coated or encrusted, for it often succeeds them. Exhaustion by discharge evidently plays a large part in the impairment of nutrition which this tongue represents. Pyrexia is not so high. The diseases with which it is associated are mostly subacute and the fevers are often hectic. Its clinical significance is prostration of some standing, often connected with material exhaustion and apt to be attended with febrile action of the hectic type. Physiologically the essential factor is failure in the growth of the lingual epithelium due to a concurrence of causes.

12. **Disposal of the Wounded in Naval Warfare.**—See "London Letter" in news department, this issue.

13. **Pulmonary Hydatids.**—O'Conor thinks that Argentina is probably only second to Australia in its frequency of hydatid disease. He has operated on 84 cases in the last 8 years, 3 of which were pulmonary, and discusses the diagnosis, localization, treatment, etc., of these cases. The diagnosis may be difficult before rupture of the cyst occurs. He does not like exploratory operations on the chest, and recommends the exploratory needle and syringe as a diagnostic agent to locate the cyst and to find its nearest point to the surface. He does this under anesthesia. His operation is described. He makes a four inch cut parallel to the corresponding ribs which are incised, the pleura opening and the presenting lung secured by bullet forceps and drawn into the wound, the exploring needle again inserted and left *in situ* to act as a guide for the knife. The intervening tissue is excised and the cut edges seized and diverted. As the fluid escapes the needle is withdrawn and the index finger introduced along the blade of the knife into the cyst. The latter is then withdrawn and two sharp hooks inserted alongside the finger and the cyst walls secured and drawn outwards. With a large, full curved needle half a dozen silkworm gut sutures are applied so as to include the cut edges of the fibrocyst with some pulmonary tissue and passed outward through the intercostal muscles and the skin, and just as they are being tied the assistant removes the bullet forceps so that the extruding portion of the lung may recede. The endocyst is removed by gentle application of a long forceps, a large rubber drain inserted and iodoform gauze applied to the wound. The after-treatment is tedious. There is a tendency to the formation of a flask shaped cavity by closure of the external wound before the cavity of the lung is obliterated. He does not believe in removal of the contents and closure of the external wound without drainage. Four cases are reported.

16. **Sleeping Sickness.**—The members of the Portuguese commission argue for their priority in the discovery of the bacterium of this disease and the identity of that described by Castellani with their own.

18. **Sodium Cinnamate.**—Drage has used sodium cinnamate in tuberculosis with success and reports a case. His experience has led him to believe that in early cases of pulmonary tuberculosis a successful issue may be predicted with confidence, and that in all more advanced cases amelioration may be guaranteed with equal confidence by this treatment. He employs a 10 per cent. solution of cinnamate of soda in glycerin, subcutaneously, 30 minims at a time. The glycerin is injected into the flank as a rule. He has also employed it in cancer with good results.

25. **Tubal Nidation.**—Kroemer states that the egg is embedded in the tube in exactly the same manner as in the uterus. It sinks through the softened mucous membrane of the tube into the fibro-muscular membranes and is completely encapsulated. Ordinarily the mucous membrane at this point rises and forms the capsule. Then the egg grows either into the lining of the tube or it separates the lining and the mucous membrane and presses the tube to the opposite side, and so lies within the muscular layer. In this case the tube is found as a small slit at the periphery of the egg. Sometimes the growth of the tube will cause a disturbance of the placenta and a hemorrhage follows which dissects the mucous membrane free from the muscular layer, and it is found as a string running through the extravasated blood. He believes that muscular contraction of the tube causes hemorrhage leading to abortion and in such cases fragments of villi may be left behind and form new growths. This fact is a point in favor of operative interference in every case of tubal pregnancy.

27. **Etiology of Birth Paralyses of the Upper Extremity.**—Eversmann cites a case of version, after which the child had paralysis of the muscles supplied by branches of the fifth and sixth cervical nerves. Suspecting a fracture, but unable to

demonstrate it, a radiograph was taken which showed a green stick fracture of the opposite or right clavicle, but no left-sided bony lesion. The child died suddenly at 2½ months without much change of condition, and the postmortem showed the healed fracture of right clavicle and a rupture of branches of the fifth and sixth left cervical nerves.

28. **Tears of the Vaginal Vault During Labor.**—Kaufmann reports 80 cases from the literature, including his own, and gives careful analysis of these. The tear is most frequently located posteriorly; its extension on the uterus complicates prognosis and treatment. The laceration is usually spontaneous, and most patients were multiparæ; in a few cases the children were oversized. In 68 cases the peritoneum was torn open; in 7 cases no report; in 5 cases uninjured. As to treatment during delivery, 20 abdominal and 2 vaginal hysterectomies were performed, and 6 laparotomies for repair of tear to peritoneum, while 9 were repaired per vaginam; 19 cases drained and tamponed; 7 were aseptic. Death occurred in 28 cases, 10 from hemorrhage and 18 from sepsis. In 40 cases of uncomplicated rupture of vaginal vault, there were 10 deaths, 2 from hemorrhage. The author shows by cited cases how almost any obstetrical operation may tear or perforate the vaginal vault or cervix. Etiologic factors are traumatism from different operations, histologic changes in the musculature and faulty mechanism or spontaneous rupture. About 40 per cent. of such tears occur in cases of transverse position of fetus. When rupture has taken place often no severe symptoms appear and the condition is found accidentally when examination is made or manual delivery of placenta attempted. Diagnosis depends on gradual cessation of pains, moderate hemorrhage and possible prolapse of intestine, confirmed by digital examination. In this condition such severe pains and collapse as in rupture of the uterus are not found. The prognosis is better than in the latter. The mortality is only 25 per cent., as contrasted with 65 per cent. in rupture of uterus. The prognosis as to the child is unfavorable. The author recommends delivery through the opening in the vaginal vault, since it does not decrease in size as does the wound in a ruptured uterus. Laparotomy is indicated only when hemorrhage is not easily controlled from below. Hysterectomy is indicated only when the uterine tear is extensive and its margins ragged and contused. The vaginal tear should be closed with suture and the drain and tampon used as needed.

32. **The Blood Mole of Breus.**—Taussig reports from Wertheim's clinic in Vienna 8 new cases of blood mole, first described by Breus in 1892. He discusses their pathology and clinical symptoms and reaches the following conclusions: 1. These moles can be divided into two classes, namely: (a), those with a pedicle where the placenta was not distinguishable, and (b) those with a broad base where the placenta was already differentiated. 2. Absence of vessels in the chorion and of the heart is not characteristic of this kind of a mole, for chorion vessels and rudiments of a heart are sometimes found. 3. The decidua is sometimes preserved; hence the cause of the malformation can not be changes in the decidua. 4. The syncytium grows after the death of the fetus, but not the Langhans' layer. 5. Amnion epithelium can also grow after death of the fruit. 6. A post-mortal growth of chorionic villi was not proven. 7. The embryo shows certain malformations, but none that can be regarded as the cause of its death. It is generally shriveled. 8. The formation of the blood mole occurs in the following way: After the death of the fetus the membranes grow and the liquor amnii increases in amount so that a secondary hydramnion occurs. Later, from unknown causes, this post-mortal growth ceases. The egg is retained and the amniotic fluid is gradually reabsorbed. The membranes become folded together, partially filled with blood, and finally a sessile or a pedicled hematoma is formed.

34. **Immunity of Animals During Pregnancy and the Puerperium in Respect to Infection and Intoxication.**—All agree that various factors like cold, loss of blood, etc., increase the susceptibility to infection. In order to determine whether pregnancy is also such a factor Bossi has experimented on 79 rabbits and guinea-pigs, some pregnant and some non-pregnant, injecting under the skin or into the veins cultures of the bacil coli, diphtheriæ, tuberculosis, etc., as well as streptococci an staphylococci. His conclusions from these observations, whic he regards as only preliminary, are as follows:

1. After infection with mixed cultures of streptococci and staph lococci or streptococci and diphtheria bacilli the number of acu infections was much greater with pregnant than with non-pregnar animals. Also the number of deaths was much greater with preg nant animals when equal amounts of the pathologic germs wer injected under similar conditions. 2. The further advanced th pregnancy, the greater were the effects of the injection. 3. Th temperature was higher after experimental infection in pregnan animals than in the control animals. 4. Abortion was commo after experimental infection. Opposite results were obtained afte experimental infection with *Bacilli diphtheriæ*; the pregnant an mals possessed the greater immunity. 5. Frequently pathogen bacteria were found in the placenta and less often in the feta blood. 6. Diphtheria toxin had less effect on pregnant animals 7. Puerperal animals showed no great susceptibility to experimenta infection. 8. Injected micro-organisms were found in the mil secretion.

The important clinical conclusion is drawn that artificia interruption of pregnancy is indicated in cases of infectiou disease like tuberculosis.

35. **Intestinal Resection for Multiple Perforation.**—Kayse reports a case of multiple perforation following the leaving of a sponge in the abdominal cavity, and cites many others, including experiments on animals. The symptoms usually are: Severe abdominal pains, peritonitis, sometimes chills, vomiting and constipation. He concludes that unless the sponge is soon removed it will initiate a fatal sepsis. As for the technic, he advocates the wedge-shaped excision with the preservation of mesentery intact, because of its ease of performance; because it is suitable for work in large intestines where the Murphy button is less practical; because in multiple resection it allows the passage without difficulty of a Murphy button if that has been used in the higher anastomosis, and because it combines rapidity with a high degree of safety. The angle caused by this anastomosis is functionally unimportant.

36. **The Sodium Chlorid-Nuclein Treatment of Puerperal Sepsis.**—Nineteen severe cases of general puerperal sepsis in Schauta's clinic have been treated with nuclein and salt solution, with one death. Nuclein in doses of 5 to 6 grams every 12 to 24 hours is given until the bone marrow reaction appears (bone sensitiveness). Five to six hundred grams of salt solution are given daily either subcutaneously or by the rectum. The recent investigations of the part played by the bone marrow in the regeneration of the blood and in the formation of immune bodies are discussed and a theory for the mode of action of the nuclein and the salt is given.

37. **Can the Bossi Method Be Regarded as an Advance in Operative Obstetrics?**—Dührssen has found in gynecologic practice that the cervix dilates to a certain point with solid dilatation and then tears easily; the same is true in obstetric work. He believes that Bossi's method, in many cases, can dilate only by producing tears, as in old primiparæ, in multiparæ having hard cervical scars, and in the premature labor of primiparæ. He cites a number of reported cases and draws the conclusions from them that in placenta previa the Bossi method is useless since it only increases bleeding, whereas the chief indication is not hastened delivery, but efficient hemostasis, which the metreurynter accomplishes well. If the cervix is obliterated in cases where the Bossi method either failed or dilated with severe tears and version or perforation had to be done, the author believes his method of incision into the cervix would have been best and harmless. He thinks the metreurynter fully as good as the Bossi instrument since it dilates, without tearing, sufficient for delivery in half an hour to one hour. In case it does not dilate, he believes the method of careful incision to be better. In cases of miscarriage where rapid emptying of the uterus is desirable and the cervix rigid, the vaginal cesarean section is preferable because of its ease and rapidity of accomplishment. If this be considered inadvisable, use the bag until some dilatation is made and then make the version according to his method. Dührssen does not believe that infection is carried in by the bag, as claimed by some, nor has he ever had trouble in introducing it. Crowding the advancing part and increasing tendency to prolapse of the cord are also urged against it, but he has never witnessed them. In either

event it is only preparatory to version and matters not. Altogether, the Bossi method is neither sure nor safe since it cannot in every case dilate sufficiently to allow delivery of a living child, and because it causes uncontrollable tears and contusions favoring infection. The author believes the best method for rapid delivery in case of obliterated cervix is by deep incisions; in case of non obliterated cervix, the use of the metreurynter and Mueller's bag with constant traction until the cervix is nearly obliterated. In case of non obliterated and rigid cervix he prefers his vaginal cesarean section.

38. **Tuberculosis of the Placenta.**—Runge reports from the literature several cases in which fetuses were tubercular, being infected through the blood and placenta. He describes the histological changes in the placenta, showing how the bacilli pass from the mother's tissue into the placenta. In the case he himself reports, the tubercular infection occurred in the decidua basalis, while in all the other cases it was found only in the layer of chorionic villi. Here no groups of bacteria were found in either the capsularis or vera, but in the broad decidua they were found around the Nitabuch layer, in the glandular layer of decidua and in a tongue of decidua projecting between the chorionic villi.

40. **Function of the Corpus Luteum.**—Gustav Born of Breslau first suggested the hypothesis that the corpus luteum of pregnancy is a gland with intrauterine secretion having the function of causing the nidation and development of the egg. Fraenkel believes that he has established this theory by experiments, and he has extended it. He holds that there is no essential difference between the true and false corpora lutea, which are ovarial glands controlling the nutrition of the uterus from puberty to the climacterium, and causing the insertion and development of the fertilized egg and of menstruation when the egg remains unfertilized. The facts favoring this theory are the gland like structure of the corpus luteum, and its growth after ovulation and the fact that only animals which have a uterine insertion of the egg possess developed corpora lutea. Experiments were made chiefly on rabbits and required considerable preliminary observation to determine the sexual physiology of these animals. By various series of experiments, in which he removed sometimes one or both ovaries, and sometimes one or all of the corpora lutea, Fraenkel determined that they are necessary to the insertion of the egg or to their development up to about 20 days. This trophic influence is exercised on the uterus by the internal secretion of the corpora lutea carried by the vessels. The influence of the so called false corpus luteum was determined on animals by burning them out, when temporary atrophy of the uterus occurred. In women in a number of cases of laparotomy for ventrofixation and similar operations, the corpora lutea were removed, with the result that menstruation remained absent for one or two periods. Therapeutic use of these facts appears in the employment of "lutein" prepared from the lutein bodies, which prevents the appearance of the premature menopause symptoms. Also in operations on the ovary during pregnancy we should preserve the ovaries and their lutein bodies as long as possible.

41. **Intrauterine Rigor Mortis.**—To the 30 cases previously reported Wolff adds 4 more from the obstetrical polyclinic of the Berlin Charity Hospital. He concludes that the occurrence of this physiological phenomenon is not extremely rare, but generally overlooked. The rigor generally reaches its climax about three to four hours postmortem. If the child remains in the uterus over five hours after its death the rigor will probably nearly or quite disappear. Particularly early and severe rigor mortis occurs where the mother is in a dying condition before or during the birth of the child. He explains this fact by assuming an extreme disturbance of the circulation in the parous woman causing a retention of metabolic products in the fetus, which, after its death, influences the early and intense development of rigor mortis. This circulation disturbance in the mother is very frequently due to eclampsia, but may result from other causes.

43. **Influence of Menstruation, Pregnancy, Labor and of the Puerperium on the Muscular Power.**—Bossi used Mosso's ergograph to determine the variations in muscular power caused by menstruation, pregnancy, etc. To determine the effect of menstruation he made daily observations for several months on a number of midwife students. Some of these ergographic curves are reproduced in the paper. They show that menstruation has a morbid influence on voluntary muscular contraction. It is particularly noticeable that the muscular strength is diminished in the period preceding the bleeding. This fact is explained by the hypothesis that toxic substances are eliminated by menstruation. Just before menstruation these toxic substances have accumulated and exercise a deleterious effect on vital functions including muscular efforts. The observations on pregnancy, labor and the puerperium were made on a number of patients. They showed that muscular strength is lessened just preceding the physiological crises of pregnancy. These crises correspond to the times when menstruation would have occurred in the non pregnant state. The effect of labor is also shown in the curves.

44. **Formation of the Enclosing Capsule in Tubal Pregnancy.** The covering of the egg in tubal pregnancy is held by some to be a decidua reflexa and by others folds of tubal mucous membrane. The study of six suitable specimens has led Voigt to the conclusion that the capsule is formed by the penetration of the egg into the maternal tissues and embedding of itself deep in the tubal walls. Thus the mucous membrane, the connecting tissues and also a part of the muscles surround and cover the ovum. In the course of further development this capsule may be so changed by the devouring action of the Langhan's cells or by hemorrhage that only band-like remnants of the walls remain. He found no trace of decidua reflexa.

46. **Cesarean Section for Eclampsia.**—Streckeisen reports two cases of cesarean section for eclampsia, both twin pregnancies. In one, both children were extracted dead and the mother died of infection. In the other both mother and children were saved. In 1897 Kettlitz collected 28 reported cases of cesarean section for eclampsia and found a mortality of 50 per cent. for the mother and 62 per cent for the children. Streckeisen has collected 28 additional cases, including his own, which show a mortality of 32 per cent. for both mothers and children. The mortality of mothers for all 56 cases is 42 and of the children 46.5 per cent. As a result of his studies he concludes that the operation has a place in the treatment of eclampsia in extreme cases.

48. **Tuberculosis of Ovarian Tumors.**—Prusman reports a case of this rare combination which is the thirteenth case now on record. Like most of the others the tumor was a cyst. Tubercle bacilli were found. He contends that the cyst in his case was secondarily infected and not that the introduction of the bacilli stimulated the growth of the cyst. On account of the absence of any signs of general or local infection, he admits the possibility of a primary infection in this case, possibly from sexual connection.

52. **Ovarian Pregnancy.**—Füth describes a case which has all the marks of ovarian pregnancy demanded by Leopold, namely, absence of ovary on the side corresponding to the tumor and its participation in the formation of the fruit sac; union of the latter with the uterus through the utero-ovarian ligament, and complete freedom of the tube including the plica infundibulo-ovarialis. A lithopedion was found on the opposite side of the abdomen. Füth considers this the twenty-first case of proven ovarian pregnancy.

53. **Bacteria in the Lochia of Normal Puerpera.**—In order to determine whether the uterine cavity is sterile or not during the first nine days of the normal puerperium, Franz undertook the examination of 120 normal puerpera, namely those whose axillary temperature never exceeded 38 C. and who had no other pathologic symptoms. The secretion was taken according to the rules of Doederlein, and all was used in the cultures. Of 20 cases examined in the first two days of the puerperium, 8, that is 40 per cent., gave positive results. Of 100 cases examined in the third to ninth days, 63 were positive. Staphylococci were found twelve and streptococci nine times. Bacteria were found more often when the temperature was under 37.5 C. than when it was between 37.5 and 38 degrees. Cases with purulent secretions were more frequently contaminated than those with bloody or serous lochia. The greater the amount of the lochia the more likelihood of a positive finding. The findings were more frequently positive in multiparæ than primiparæ. There was less liability to contamination when the labor was protracted. The conclusions from this investigation are that there is no relation between contamination of the uterine cavity and the clinical symptoms, or in other words, the presence of bacteria in puerpera without fever is not pathologic.

54. **Indications for the Total Extirpation of the Septic Uterus.**—Baisch first considers the danger on account of sepsis of the complications of labor with complete inversion of the vagina with elongation of the neck of the uterus. In only 31 cases of 124 reported in the literature was labor spontaneous. The mortality of the children was 30 per cent., and of the mothers about 11 per cent. In two cases of Doederlein's clinic in Tübingen hysterectomy probably saved the patient's lives, while in one where operation was refused, the patient died. Baisch concludes that in cases of total prolapse when fever exists during labor, hysterectomy is indicated. A discussion of other indications leads to the conclusion that cases of mixed infection and saprophytic disease call most often for surgical interference because intoxication from the latter makes it very difficult for the organism to successfully combat the infection.

55. **Posterior Parietal Presentation.**—Zangemeister divides the cases into primary and secondary, depending on whether the membranes are intact or not. Primary cases are rather common and generally terminate spontaneously. In 2,250 labors 10 cases of secondary posterior parietal presentation occurred (equal to .44 per cent.), 2 of which terminated spontaneously. He concludes that turning is best when the presentation does not improve in a short time. If turning is impossible on account of danger of rupture, spontaneous delivery may be waited for under certain conditions. Symphysiotomy is in these cases valuable. External or combined rectification is almost always impossible. High forceps is allowed only as a trial before perforation of a living child.

59. **Diagnosis and Treatment of Genital Tuberculosis in Women.**—Sellheim calls especial attention to Hegar's sign of pelvic tuberculosis found by internal examination, namely, presence of numerous nodules from the size of a pin's head to a lentil on the ligamenta sacro-uterina, the posterior surface of the uterus and of the ligamenta lata. Operative treatment should be instituted only when thorough general and local treatment fail to stop the progress of the infection. To determine the value of both methods Sellheim has studied the results in cases treated in the Freiburg clinic during the last eight years. There were 31 palliative and 27 operative cases. He found the results of the palliative treatment satisfactory as far as disappearance of pain, ability to work and shriveling of diseased organs were concerned. In the operative cases he found the best results in the radical operations where both adnexa and uterus were removed.

60. **Cancer Inoculation in the Genital Tract.**—Hellendall concludes that no case of cancer metastasis in the vagina through inoculation from a corpus or a cervix cancer has been proven to occur, and that the probability of such an inoculation can not be assumed since a careful microscopic examination has not excluded the possibility of distribution of the cancer in a retrograde manner through the veins and lymphatics.

63. **Treatment of Uterus Rupture.**—Zweifel holds it very important to distinguish between complete and incomplete rupture. For the latter, drainage is a satisfactory treatment, but not for the former. He recommends here laparotomy and careful suture of the serosa *not including the musculature* which should always be regarded as infected. After recovery the patient may be sterilized by excising a piece of each tube to prevent rupture in a subsequent pregnancy. After suturing the tear the peritoneal cavity should be carefully cleaned from blood. He reports 29 cases from his clinic.

64. **Vaginal Ovariotomy.**—Heinsius describes the technic adopted by A. Martin and discusses the indications for operation and the complications which may arise. A table is given of the 110 cases operated on at Greifswald.

65. **Accidental Injuries During Gynecologic Operations.**—The effort made in recent years to increase the thoroughness of operation for malignant disease has resulted in an increase in the injuries to neighboring organs, namely, the ureters, the bladder, and the bowels. A study of the accidents that have occurred at Chrobak's clinic in the last twelve years has been made by Blau. They are classified, compared with those of other clinics as far as possible, and their treatment considered. In 2,193 operations 45 (equal to 2 per cent.) accidents have occurred. The ureters were injured 15 times, bladder 21 times and bowels 14 times. The mortality of ureteral injuries was 80 per cent., of bladder injuries 43, and of bowel injuries 78 per cent. Of the 45 operations 24 were laparotomies with 26 injuries, including 10 of the ureters, 7 of the bowels, and 9 of the bladder. Twenty were vaginal operations, with 23 injuries, including 4 of the ureters, 12 of the bladder and 7 of the bowels, and one was a sacral hysterectomy with 1 injury to the ureters.

66. **Extrauterine Pregnancy at Term.**—Freund reports a case of unruptured tubal pregnancy at term with a fungiform placenta, and discusses the features of this rare case (only four others are known). The chief conclusion from the study is that where the placenta is inserted on the mesosalpinx it takes a fungus form whose stalk is formed by the vascular tubal wall. On account of the great development of the vascular apparatus the musculature can remain intact to the end of pregnancy. Freund also reports a case of *lithokelyphopedion* and gives a table of 10 other cases known.

69. **Radical Treatment of Hernias on Linea Alba.**—Menge has recently operated on two very large umbilical hernias and one subumbilical, by a modification of Bioñdi's method of combined vertical and transverse incision. He aimed to produce a very broad, flat adhesion of the fascia to the muscle at the point of the previous hernia, and the results confirmed his assumption that this technic would impart great solidity to the cicatrix. The anterior lamella of the sheath of the rectus was incised across to a distance of 3 or 4 cm. on each side of the hernial opening, the rectus itself divided lengthwise with the fingers and the posterior lamella of the sheath also incised across. Each lamella was then sutured across; the rectus with a vertical suture. The wound healed rapidly by primary intention in each case, but further experience will show whether this technic allows the development of a hematoma under the fascia, and whether the circulation in the fascia and muscles will be impaired.

70. **Lateral Symphysiotomy.**—Meyer reports a case in which he performed pubiotomy or extramedian symphysiotomy according to Gigli's technic. The child had been born dead in a previous pregnancy, terminated by obstetric maneuvers. At term, with the second pregnancy, the rachitic pelvis measured only 7 to 7.5 cm., labor was energetic and head movable above the inlet, which it was unable to enter. Instead of making an oblique incision, Meyer incised vertically, inserting his finger from below and catching with it the wire saw introduced from above. The sawing was thus parallel to the median line and proceeded with surprising ease. The child was then extracted without difficulty, the bone gaping about 5 cm. The pubis was sutured with silver wire, with a small drain tube left at the lower angle of the wound, removed the sixth day. There were no urinary disturbances except that catheterization was necessary for four days. The union seemed solid by the seventeenth day and the patient was allowed to get up the twenty-first. The gait is free and natural and she can stand on either foot alone without trouble. There has been no displacement of the bones. The child weighed 3,700 51 gm. This is the fourth pubiotomy Meyer has done and all the patients rapidly recovered. He mentions that the treatment after an operation on the symphysis or pubis is much facilitated by the Borries litter, made at Copenhagen. He suggests as the only drawback to this extramedian symphysiotomy, the possibility that the circulation of the small fragment of bone left adherent to the symphysis may be interfered with. His experience indicates that the circulation is adequate, but time alone can fully decide the question. (Gigli's communication on the subject was reviewed in The Journal, xxxix, p. 226.)

71. **New Method of Prolapse Operation.**—Rieck is able to ensure complete relief and freedom from recurrence even in cases of total prolapse of uterus and vagina. The uterus is detached from the bladder and the latter with its peritoneal covering is fastened on the posterior surface of the uterus, while the anterior wall of the vagina is sutured to its anterior surface and up over the top of the fundus. As the uterus is thus fastened in extreme anteflexion between the bladder and vaginal wall there can be no further prolapse, and the bladder is prevented from pushing down the vaginal wall as the uterus is interposed. The rear wall of the vagina is sutured to the perineum and does not show even if it may stretch a little. In case of women still in the child-bearing period a less radical procedure is preferable. In this case the anterior wall of the vagina is incised on the median line and the two halves superposed, thus doubling the wall of the vagina along this part. The detached mucosa with its raw connective tissue surface healed perfectly to the epithelium surface in the 4 cases that have been treated according to this technic. No tendency to further prolapse could be discovered three weeks after dismissal. Two of the patients had total prolapse of both uterus and vagina, and the operation was completed by low vaginofixation in the younger patient and high fixation in the patient at the climacteric age. It remains to be seen whether this doubled vaginal wall will interfere with childbirth later.

72. **Retention of Fetus After Laceration of Uterus.**—A v-para was injured in the abdomen during the seventh month of pregnancy and the movements of the fetus were no longer perceptible after the traumatism. Six weeks of good health followed, after which she applied for treatment on account of severe pains in the abdomen and slight fever. Investigation revealed a tear in the anterior wall of the cervix and in the cavity thus formed the remains of a seven-month fetus. No placenta could be discovered. Goth ascribes the rupture to the traumatism, and thinks that the uterus was rendered incapable of labor and behaved like a loose sac, as in an extrauterine pregnancy. This explains the absence of any indications of labor.

74. **Impregnation.**—Toff is convinced that the female organism is more or less essentially altered by the reception of the male semen in considerable amounts, and becomes in time impregnated with the organic juices or chemical combinations of the male organism. This influence is particularly marked, he thinks, during and following pregnancy. Elderly virgins and women who prevent conception are liable to suffer from various affections which are possibly due to the lack of the vital forces which normally are transmitted from the male to the female organism. On the other hand, the influence of the male organism may be detrimental in case it is diseased. Women, healthy until marriage, sometimes suffer from headaches, anemia, nervous affections, etc., which may be due to toxins transmitted in this way from the male. He suggests that this may prove to be one of the factors in uncontrollable vomiting of pregnancy, eclampsia, kidney affections, etc. The closer to nature the life of the people, the healthier are the men and women and the smoother the course of pregnancies and childbirth.

76. **Pessary for Large Inoperable Prolapse.**—Menge's instrument is a large oval ring with a crossbar. A pear-shaped knob fits into a hole in the center of this crossbar, after the ring has been inserted in the vagina. By its introduction in two parts, it is thus possible to use a larger ring than would be otherwise applicable, and it proves an effective obstacle to further prolapse. He calls it the "Keulenpessar," as the knob resembles somewhat the pestle of a mortar. It fits into the crossbar with a bayonet catch, and holds the ring perpendicular to the axis of the vagina.

80. **Vaginal Cesarean Section in Eclampsia.**—Duhrssen describes a case in which he delivered a primipara in severe eclampsia of a child weighing 4,500 gm. with a head circumference of 37 cm. The vagina was very narrow, but the entire operation was complete and the child extracted in eight minutes. The wound healed by primary intention; involution of uterus proceeded apparently normally and recovery was rapid. There were no convulsions after delivery. He recommends in primiparæ to previously incise the vagina, making the opening in both vagina and uterus large enough to admit a man's fist. He points out that his operation is both intra- and supravaginal, as well as bilateral on the uterus. Through the anterior incision in the vaginal wall he detaches and pushes back the bladder and processes of peritoneum without opening the

abdominal cavity, and thus frees the wall of the uterus so that after it is incised a large child can be delivered alive, as he has accomplished in his 4 cases.

82. **New Sign of Multiple Pregnancy.**—Jentzer was able to palpate two fetal heads, and mentions that when they were brought in contact they felt like billiard balls knocked together in water. In the case described the woman was delivered of triplets, but the third fetus escaped detection. This and a following birth proceeded normally, although she had been previously treated by ventrofixation for painful retroflexion. In 5 other cases of childbirth consecutive to ventrofixation the course of the pregnancy and puerperium was normal in every respect.

84. **Strychnin in Ileus.**—Grube attributes the favorable result in the case he reports to his subcutaneous administration of .01 gm. strychnin nitrate in three doses in four hours, followed six hours later by .005 gm. Peristalsis was excited; the heart symptoms subsided and the patient soon recovered. The ileus was due to severe paralysis of the intestines subsequent to removal of a purulent sacrosalpinx with suppurative encapsulated peritonitis. He adds that this case emphasizes the advantages of vaginal intervention, as the peritonitis remained circumscribed, and was not spread over the entire peritoneum as liable with a laparotomy.

86. **Self-Holding Speculum.**—Spiegel's instrument screws to the edge of the table and the speculum part is adjustable at any angle. It dispenses with the presence of an assistant to hold the speculum, and has never caused trouble of any kind during several months' experience with it in constant use at Schauta's clinic.

88. **Nerve Grafting.**—In operating on a suppurating temporal bone, the facial nerve was severed at the stylomastoid foramen, and the distal stump was fastened side by side to the hypoglossal nerve. The facial and hypoglossal domains were paralyzed for six months, the former totally, the latter partially, causing some slight disturbances in swallowing. Then gradual improvement was noted, electric excitability gradually returned, and the corner of the mouth can be now actively moved. The voluntary impulse is thus successfully transmitted to the facial muscles by way of the hypoglossal, and further improvement is anticipated in time. The partial paralysis of the hypoglossal shows that only a healthy nerve can be utilized for such grafting. The tongue still moves involuntarily with the voluntary movements in the facial domain, nearly a year after the operation, as in Kennedy's case, in which the facial muscles moved as the trapezius was contracted. Körte, in future, would choose the accessory nerve instead of the hypoglossal in such a case as paralysis in its domain is of much less importance than in the hypoglossal.

90. **Stains for Malaria Parasites.**—Koreck gives a number of formulæ for stains and shows that the age of the solution as also the amount of heat to which it has been subjected, have an influence on the result of the stain. His improved Ziemann stain is made by adding .5 gm. collargol to 100 c.c. of a 1 per cent. solution of methylene blue and using it in the proportion of 1 to .6 of the eosin solution. The resulting stain is fine in fifteen minutes or less.

94. **Production of Specific Substances from Bacteria.**—Brieger has found that it is possible to derive from a solution of typhoid cultures a non-toxic substance which confers high agglutinating power on rabbit serum, but no bactericidal or protecting properties. He describes his technic.

95. **Paratyphus.**—Kayser reports 3 cases of apparent typhoid fever in which the serum agglutinated the paratyphus bacilli, type B, while it had no effect on true typhoid bacilli. Two of the patients were sisters about 25, the third a child of 8. There was no albuminuria, but severe headache in the 2 first and edema of the lids and painfulness of the spine in the latter case. He adds that experience with these paratyphus cases to date indicates that the infection is mild, but that in testing for the agglutination both type A and type B of the paratyphus bacillus must be tested. He protests against the use of the term typhoid instead of typhus, claiming that the former should be restricted to "ileotyphus."

98. **Electromagnetic Treatment of Trigeminal Neuralgia.**—Lilienfeld has cured 11 and materially improved 65 out of a total of 90 cases of trigeminal neuralgia treated by electromagnetic seances. Almost all his patients had suffered for years from neuralgia, some for ten to twenty-five. He describes 7 typical severe cases in detail. In one the pain was mitigated after the fifth application of the alternating magnetic field, 15 amperes. By the fifteenth the patient was freed from pain during the day, and by the thirtieth entirely relieved except for occasional comparatively slight twinges during the night. Treatment was interrupted at this point, but the improvement has continued for three months to date. In another very severe case after twelve years of suffering the patient was dismissed completely cured by a course of 50 applications. All these chronic cases had been previously treated with the usual measures without avail, and even if the neuralgia should return later, the months of freedom from pain are certainly an immense gain.

100. ***Primary Gangrenous Angina.***—The patient was a lad of 12 who had passed through measles and typhoid in early childhood. The malignant angina developed with exacerbations. The first stage was characterized by pains in ear and neck on right side, subsiding after a week; two weeks later pains occurred in the ear and neck, and the tonsil, palate and uvula on the left side were found to be ulcerated. The ulcerations healed and for ten days there was no further trouble, but then a gangrenous abscess developed in the right tonsil, and ten days later in the left. The spleen was enlarged. The angina retrogressed by the end of ten days, leaving merely a whitish deposit on the right side of the throat. A few days

later severe symptoms again appeared, with high fever, pains in the left side of the neck and petechiæ. This stage also subsided, and for a month the little patient seemed well, except for a transient attack of heart weakness. The fifth and fatal stage then set in and the gangrene in the throat spread with a fatal termination in ten days. The petechiæ during the last three stages were noticeable, as also a severe hemorrhage from the retina during the terminal stage. Numerous internal hemorrhages were also observed at the autopsy. In this, as in 2 other cases on record, a loud systolic murmur was heard during the last stages of the affection, but the assumption of a vitium cordis was not confirmed by the autopsy. Treatment had been energetic, with lactic acid, etc.

103. Artificial Production of Pleural Adhesions for Surgical Purposes.—Karewski proclaims that he has succeeded in inducing effective adhesion by means of a combination of chemical irritation, trauma and prevention of displacement of the sheets of the pleura. He accomplishes this by the use of silk threads impregnated with turpentine, uniting the interspaces with the lung pleura. The turpentine suture attracts the leucocytes and entails a deposit of fibrin, thus walling off the part of the lung desired with a broad sheet of adhesions or merely a circular wall, according to the way the sutures are applied, either parallel through the interspaces or circular around the focus. His experiments were made on large dogs, and he found that in three days firm union was realized by this means over a flat surface. Linear adhesions required a few more days to form a strong enough wall. He thinks that the conditions in man would be much more favorable for the formation of adhesions by this technic.

105. Volumetric Determination of Albumin.—Rössler states that it is possible to determine the amount of albumin in the urine, even in a proportion of 1/120,000, by means of a mixture of 2 parts succinic acid, 1 part sublimate, .1 part sodium chlorid and 50 parts distilled water. Three drops are added to 5 c.c. of dilute acetic acid and the urine added to form a layer, as in the potassium ferrocyanid test, of which this is a modification. The height of the white zone that forms from the combination with albumin indicates the amount of the latter. It is measured with a compass and by comparison of the results obtained at rest, after exercise, medication, baths, etc., a characteristic curve is obtained. The increase in the amount, after walking for an hour, after two hours' mountain climbing, etc., was much more marked in case of kidney disease, and the method is thus able to reveal the latter in its incipiency. Kussmaul adopted the following system: the first day the albumin was determined during complete rest; the second day after an hour's walk and the third day after two hours' moderate mountain climbing. In case of mere spermatorrhea the curve was flat or dipped slightly down, as was also the case when the albumin was due to the presence of pus in the urine, but in case of kidney disease, the curve rose each day, and the third day was nearly three times the height of the first day. In case of kidney disease with spermatorrhea the ascent to the third day was more gradual and not so high at the last, as in case of kidney disease alone. In case of a suppurative affection of the bladder or uterus in addition to the kidney affection, the height of the zone was above that of the other curves on the first day and considerably higher on the two following days. The curves thus obtained correct many a mistaken diagnosis. In one instance they contradicted the assumption of a kidney affection for which the patient had been treated elsewhere for two years. Catarrh of the uterus was diagnosed and the patient promptly cured by appropriate treatment.

106. Thoracoplastic Operation and Disinfection of Lung Cavities.—Spengler advocates disinfection of the lungs in case of tuberculosis or other severe affections of the respiratory passages, by means of inhalation of a mixture of 5 c.c. formalin, 20 c.c. absolute alcohol and 75 c.c. ether. Ten drops of this mixture are poured into a tumbler and inhaled in ten deep breaths through the opened mouth once every second day, or five drops morning and evening on alternate days. After fourteen days of these inhalations he suspends them for several days. He has never seen any harm from these doses even when long continued, and some of his patients inhaled as much as forty drops six times a day, but he found that these larger amounts depressed the vitality and thus favored bacterial proliferation. He, therefore, warns against more than ten drops on alternate days, continued with interruptions until the bacilli have disappeared from the sputum. In case of laryngeal tuberculosis, once in three days is probably sufficient and caution is also needed with nephritic patients. Pure formalin is too irritating and not volatile enough. Even in advanced cases the measure is useful for the protection of others. It should be used in all cases of cavity formation with rigid walls and inadequate evacuation of the products in the cavity. In case it fails to relieve after thorough trial, he urges resection of ribs to mobilize the thorax and thus allow the parts to expand and contract. But the inhalations will frequently reduce the suppuration to such a point that intervention is not required and many cases of phthisis with cavities heal in a remarkably short time. He has performed such a thoracoplastic operation eight times and one of the patients is clinically cured. All were cases of severe bilateral infection. His experience indicates that the sweats in tuberculosis aid in the absorption and elimination of the exudate in the lungs, and should not be suppressed. The amount of sputum in twenty-four hours and physical examination are aids for locating and measuring the size of the cavity. Inhalation of the "F.-A.-E. mixture" described above causes, in isolated cases, rapid decrease in the amount of sputa and number of bacteria, both the tubercle bacilli and others, but this occurs only in favorable circumstances. When there is active mixed infection, the germs ensconced deep in the parenchyma of the lung, inaccessible to the formalin vapors, the results will be meager or negative. He illustrates and describes the technic of the thoracoplastics which he recommends.

108. Pulsus Paradoxus.—Riegel distinguishes three causes for this condition. In the first group it is the result of compression of the large vessels from the effects of mediastino-pericarditis. The swelling of the veins in the neck during inspiration is important in the differentiation of this group. The heart is not implicated in the production of the paradoxical pulse but rather works with extra energy on account of the resistance in the aorta. The apex beat is not weaker during inspiration but stronger than usual, as also the heart sounds. In the two other groups the pulsus paradoxus is the expression of impaired heart action. In one the cause is interference with the intake of air, as in laryngeal stenosis, pneumonia, capillary bronchitis, etc. As the air can not enter freely, the negative pressure during inspiration is increased, and the *normal inhibiting influence* of inspiration on the heart is unduly magnified. If tracheotomy is done the paradoxical pulse disappears at once. In the other of these two groups the cause is to be sought in the enfeeblement of the heart, which is unequal to its task. In such cases the paradoxical pulse may vanish on exhibition of digitalis. Distinction of these three types of causes is important for treatment, although it is possible for two or more of them to be associated in a case.

109. Relations of Mild Infections to the Blood-Forming Apparatus.—This communication from Koch's Institute for Infectious Diseases announces that minute doses of infectious germs, so small as to be unable to produce any symptoms in the laboratory animals, yet exerted a specific influence on the blood-forming apparatus, stimulating it to unusual activity. Even a very mild infection, therefore, may be able to excite this apparatus to abnormal functioning, a fact important for the clinic. Not only the bacteria but even their dissolved toxic products exerted this influence. This fact may explain the puzzling anemias noted in chronic obstipation. Also the abnormal heart action, the nervous symptoms, general and local, the depression, etc., may be due to absorption of toxic substances from the intestines and to their influence on the blood-forming apparatus, as whenever this apparatus is unable to fulfill the extra demands on it, its functions must suffer, and principally the regeneration of the blood. Many puzzling cases of anemia and chlorosis may be the result of some apparently insignificant infection and its effect on the hematopoietic organs. In such cases infection in the respiratory, digestive and female genital organs must be excluded before we can institute appropriate treatment.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

International Clinics. A Quarterly of Illustrated Clinical Lectures, and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otology, Rhinology, Laryngology, Hygiene, and Other Topics of Interest to Students and Practitioners, by Leading Members of the Medical Profession Throughout the World. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia, U. S. A. With Regular Correspondents in Montreal, London, Paris, Berlin, Vienna, Leipsic, Brussels and Carlsbad. Volume I. Thirteenth Series, 1903. Cloth. Pp. 306. Price, $2.00. Philadelphia: J. B. Lippincott Co. 1903.

A System of Physiologi [illegible] A Practical Exposition of the Methods, Other [illegible], Useful for the Prevention of Disease and in the Treatment of the Sick. Edited by Solomon Solis-Cohen, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College. Volume X. Pneumotherapy, Including Aerotherapy and Inhalation Methods and Therapy. By Dr. Paul Louis Tissier, One-Time Interne of the Paris Hospitals. Illustrated. Cloth. Pp. 479. Price, $27.50 per set. Philadelphia: P. Blakiston's Son & Co. 1903.

The Surgical Diseases of the Genito-Urinary Organs. By E. L. Keyes, A.M., M.D., LL.D., Consulting Surgeon to the Bellevue, and E. L. Keyes, Jr., A.B., M.D., Ph.D., Lecturer on Genito-Urinary Surgery, New York Polyclinic Medical School and Hospital. A Revision of Van Buren and Keyes' Text-Book. With 174 Illustrations in the Text and 10 Plates, 8 of Which Are Colored. Cloth. Pp. 827. Price, $5.00. New York and London: D. Appleton & Co. 1903.

Bacteriology. A Manual for Students and Practitioners. By Ferd. C. Zapfee, M.D., Professor of Pathology in the Illinois Medical College. Series Edited by Bern B. Gallaudet, M.D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, Columbia University. Illustrated with 146 Engravings and 7 Colored Plates. Cloth. Pp. 350. Price, $1.50 net. Philadelphia and New York: Lea Brothers & Co.

Diseases of the Heart and Arterial System, Designed to Be a Practical Presentation of the Subject for the Use of Students and Practitioners of Medicine. By Robert H. Babcock, A.M., M.D., Professor of Clinical Medicine and Diseases of the Chest, College of Physicians and Surgeons, Chicago, Ill. With 3 Colored Plates and 139 Illustrations. Cloth. Pp. 853. Price, $6.00. New York and London: D. Appleton & Co. 1903.

Practical Handbook of the Pathology of the Skin. An Introduction to the Histology, Pathology, and Bacteriology of the Skin, with Special Reference to Technic. By J. M. H. MacLeod, M.A., M.D., M.R.C.P., Assistant in the Dermatological Department, Charing Cross Hospital. With 8 Colored Plates and 32 Black and White Plates. Cloth. Pp. 408. Price, $5.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A Practical Treatise on Materia Medica and Therapeutics. By Roberts Bartholow, M.A., M.D., LL.D., Professor Emeritus of Materia Medica, General Therapeutics, and Hygiene, in the Jefferson Medical College of Philadelphia. Eleventh Edition, Revised and Enlarged. Cloth. Pp. 866. Price, $5.00. New York and London: D. Appleton & Co. 1903.

Hygienic Laboratory. Bulletin No. 10. M. J. Rosenau, Director. February, 1903. Report on the Prevalence and Geographic Distribution of Hookworm Disease in the United States. By Ch. Wardell Stiles, Ph.D., Chief of Division of Zoology. Paper. Pp. 121. Washington: Government Printing Office. 1903.

Wild Oats. A Sermon in Rhyme. By Maurice C. Hime, M.A., LL.D., Sometime Head-Master of Foyle College, Derry. Cloth. Pp. 49. Price, One Shilling. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

Transactions of the American Roentgen Ray Society. Third Annual Meeting, Chicago, Ill., December 10 and 11, 1902. Paper. Pp. 178. Louisville: Courier-Journal Job Printing Co. 1903.

The John Crerar Library. Eighth Annual Report. For the Year 1902. Paper. Pp. 45. Chicago: Printed by Order of the Board of Directors. 1903.

Practical Synonyms. By John H. Bechtel. Cloth. Pp. 226. Chicago, New York and London: Page Davis Co.

Second Annual Report of the Lewis Hospital of Bay City, Mich., Jan. 15, 1903. Paper. Pp. 25.

The Public Service.

Army Changes.

Movements of officers of the Medical Department, U. S. A., under orders from the Adjutant General's Office, Washington, D. C., for the week ending May 30, 1903:

Ashburn, James K., contract surgeon, is granted an extension of leave for ten days.

Farr, Charles W., first lieut. and asst.-surgeon, granted leave January 28, has extension of two months, and is changed to two months' sick leave from April 26, 1903.

Fanning, George J., contract surgeon, is granted an extension of leave for one month from May 22.

Gorgas, William C., colonel and assistant-general, now on leave in New-York City, will report on June 1 to the commanding general, Department of the East, for temporary duty as chief surgeon of that department during the absence on leave of Colonel Henry Lippincott.

Gregory, William G., contract surgeon, is granted leave for one month on surgeon's certificate, with permission to leave the Department of California and is granted permission to apply for an extension of one month.

Godfrey, Guy C., captain and asst.-surgeon, is relieved from further duty in the Division of the Philippines, and will proceed to San Francisco, Cal., and report by telegraph to the Adjutant General of the Army for further orders.

Jones, George H., contract surgeon, now on leave at Toledo, Ohio, is relieved from further duty in the Division of the Philippines and will proceed to Fort Fremont for duty, to relieved Contract Surgeon J. Randolph Harmer, who will proceed to Fort Totten for duty.

McCulloch, Champe C., Jr., captain and asst.-surgeon, is relieved from further duty in the Division of the Philippines and will proceed to San Francisco, Cal., and report by telegraph to the Adjutant General of the Army for further orders.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 29, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, May 16-23, 4 cases.

California: Los Angeles, May 8-16, 1 case; San Francisco, May 10-17, 2 cases.

Colorado: Denver, April 25-May 2, 19 cases.

Illinois: Belleville, May 16-23, 1 case; Chicago, May 16-23, 9 cases.

Indiana: Elwood, May 17-24, 6 cases; Indianapolis, May 16-23, 3 cases.

Iowa: Des Moines, May 16-23, 1 case.

Kentucky: Newport, May 8-23, 2 cases.

Louisiana: New Orleans, May 16-23, 4 cases.

Maine: Biddeford, May 16-23, 1 case.

Maryland: Baltimore, May 16-23, 1 case.

Massachusetts: Holyoke, May 16-23, 1 case.

Michigan: Detroit, May 16-23, 25 cases, 1 death; Grand Rapids, May 16-23, 1 case; Port Huron, May 16-23, 1 case.

Minnesota: Winona, May 16-23, 3 cases.

Missouri: St. Louis, May 17-24, 20 cases.

Nebraska: Omaha, May 16-23, 1 case.

New Hampshire: Manchester, May 16-23, 4 cases; Nashua, May 16-23, 6 cases.

New Jersey: Camden, May 16-23, 1 case.

New York: Elmira, May 16-23, 1 case; New York, May 16-23, 1 case; Rochester, May 14-21, 6 cases.

Ohio: Ashtabula, May 16-23, 2 cases, 1 death; Cincinnati, May 15-22, 15 cases; Dayton, May 16-23, 5 cases.

Pennsylvania: Altoona, May 16-23, 1 case; Carbondale, May 14-21, 1 case; Johnstown, May 16-23, 1 death; McKeesport, May 16-23, 1 case; Philadelphia, May 16-23, 18 cases, 4 deaths; Pittsburg, May 16-23, 24 cases, 3 deaths, 1 case imported from West Virginia; Reading, May 18-25, 1 case.

South Carolina: Charleston, May 16-23, 10 cases, 1 death.

Utah: Salt Lake City, May 16-23, 3 cases.

Wisconsin: Milwaukee, May 16-23, 1 case.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, April 26-May 3, 1 death.

Canada: Winnipeg: May 9-16, 1 case, 1 death.

Canary Islands: Las Palmas, April 25-May 2, 18 cases.

China: Hongkong, March 28-April 11, 2 cases, 1 death.

Colombia: Barranquilla, May 3-10, 3 deaths: Bocas de Toro, May 25, 25 cases, 2 deaths.

Great Britain: Birmingham, May 2-16, 24 cases; Dublin, May 2-9, 27 cases, 4 deaths; Dundee, May 2-9, 1 case; Glasgow, May 8-15, 1 case; Leeds, May 2-16, 34 cases, 3 deaths; Liverpool, to May 16, 6 deaths; London, May 2-9, 17 cases; Manchester, May 2-9, 10 cases, 1 death; Newcastle-on-Tyne, May 2-9, 1 case; Nottingham, May 2-9, 2 cases; Sunderland, May 2-9, 1 case.

India: Bombay, April 21-28, 94 deaths; Calcutta, April 18-25, 3 deaths; Madras, April 18-25, 1 death.

Mexico: City of Mexico, May 10-17, 11 cases, 7 deaths.

Russia: Moscow, April 25-May 2, 2 cases, 1 death.

Spain: Valencia, April 15-30, 2 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, April 26-May 3, 13 deaths.

Colombia: Panama, May 11-18, 3 cases, 1 death.

Costa Rica: Limon, April 30-May 14, 5 cases, 2 deaths.

Mexico: Coatzacoalcos, May 8-16, 1 case; Tampico, May 8-16, 1 death; Vera Cruz, May 16-23, 12 cases, 7 deaths.

CHOLERA.

India: Calcutta, April 18-25, 140 deaths.

Straits Settlements: Singapore, April 4-11, 3 deaths.

PLAGUE.

Brazil: Rio de Janeiro, April 26-May 3, 2 deaths.

Chile: Iquique, May 27, present.

China: Hongkong, January 1-April 11, 216 cases, 208 deaths.

India: Bombay, April 21-28, 1,031 cases; Calcutta, April 18-25, 434 cases; Karachi, April 19-26, 228 cases, 197 deaths.

Japan: Yokohama, May 26, present.

INDICATIONS FOR CHOLECYSTECTOMY.[*]

BYRON B. DAVIS, M.D.
Professor of Principles of Surgery and Clinical Surgery, College of Medicine, University of Nebraska; Surgeon to Immanuel and to Wise Memorial Hospital.
OMAHA.

The primary object of every surgical operation is to secure the completest and quickest relief compatible with safety. If it can be shown that in certain specified conditions of the gall bladder cholecystectomy is followed by more perfect restoration to ideal health, by a prompter convalescence, and that the mortality is no greater than in cholecystostomy, my point is made.

Cholecystostomy is frequently disappointing, the hoped-for benefits are only partially realized and the patient still has pain. Of my last twenty-eight cholecystostomies, six are known to have pain, not so severe as before the operation, but enough to be a source of worry and inconvenience. This means more than 20 per cent. of failures to accomplish fully what was attempted. Hans Kehr reports that in more than 17 per cent. of his cholecystostomies the relief was only partial. Others report the same disappointing results.

When we face squarely the fact that in any operative procedure there is to be considered not only the primary mortality but also the knowledge that about one patient out of five will be only partially relieved, some of them indeed almost as great sufferers as before, it is a humiliation to surgical pride. If improvement in technic will not give better results, no true surgeon will be satisfied until some other measure is found more satisfactory, really curative.

A prolonged convalescence, though not an insuperable objection to an operative procedure, if finally followed by entire relief, is to be deplored. After draining the gall bladder till the infection is removed the fistula quickly closes in many cases, but in a startling number a chronic fistula follows, most of them finally healing, but after so long and disagreeable delay that many times the patient regrets ever having the operation. In the twenty-eight cases of drainage mentioned three fistulæ discharged for many months, but finally healed; one is still discharging after six months, and three continued to discharge until cholecystectomy was done. Twenty-five per cent. of chronic fistulæ seems a good many, but it occurred in this series and, judging from the number of fistulæ I have seen after operations by other surgeons, the conclusion can not be dodged that this is a standing opprobium to this form of operation.

In simple uncomplicated cases the operative mortality for cholecystostomy ought to be very low. Kehr gives his as 2 per cent. In the cases complicated by dense adhesions, atrophy of the gall bladder, acute infections and the like, the mortality is considerable. Kehr admits a mortality of 47 per cent. in this class of cases. Some of his cases were operated on a number of years ago. With the present perfected technic it is probable that it would be considerably less, though bound always to be high. The fact can not be evaded that with the serious complications met in all old cases and in the acute infections (empyemas, gangrene, etc.), the dangers from any operation are great, and in many we must be satisfied to do what will tide the patient over until in such condition as to be able to withstand such an operation as will bring relief.

Kehr has found that less than 1 per cent. of his cholecystectomies continued to have symptoms. All the rest were completely cured. Absence of all disagreeable sensations has been noted in all of my cases in which cholecystectomy has been done, though in two of them still under treatment it is too early to know the result.

After cholecystectomy the convalescence is very rapid. As a rule there is no discharge, though in occasional cases where infection of the ducts is present, closure of the cystic duct has not been deemed advisable. Even in cases drained in this manner healing has been prompt. No mucous fistula due to a diseased gall bladder poorly drained has been present. In ten out of twelve cases the wound has been closed in a week to ten days.

Kehr's operative mortality for cholecystectomy is 3.3 per cent., as against 2 per cent. for uncomplicated cholecystostomies. There is abundant reason to believe that many of his cholecystectomies would be considered complicated, so this seems an excellent showing for cholecystectomy. In my own cases since Jan. 1, 1902, there have been twelve uncomplicated cholecystostomies, with no deaths; sixteen complicated cholecystostomies, with three deaths (one of these I feel certain would have recovered had cholecystectomy been done); twelve cholecystectomies, with one death, a very badly complicated case.

Why are so many cases uncured after cholecystostomy? The answer to this question I believe to be found in the amount of pathology left behind. Adhesions to the pylorus cause dragging on the stomach, with resulting gastric symptoms. Adhesions to the intestines produce painful sensations during active peristalsis. There are often a number of conditions of the gall bladder following cholecystostomy, which seriously interfere with perfect emptying of the viscus: 1, Adhesions to neighboring viscera; 2, crippling of the gall bladder from inelasticity of its walls; 3, partial occlusion of the cystic duct; 4, interference with the perfect contraction of the walls during the effort to empty itself, due to the fundus being fixed to the anterior abdominal wall; 5, the weight of the liver pressing down on the anchored gall bladder.

---

[*] Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

The number of cases demanding surgery of the gall bladder in which the cystic duct is normal and in which the mucous membrane is intact and the walls normally elastic, is only a small minority. Such cases will usually close promptly after simple drainage. But when any of the above conditions are present, prolonged and imperfect convalescence is to be expected.

The advantages of cholecystectomy are to be found in all the conditions which render cholecystostomy unsatisfactory and disappointing: 1, When the cystic duct is wholly or partially occluded healing is prompt and complete; 2, when the wall of the gall bladder is thickened, friable and atrophied, the functionless viscus is taken out and can no longer torment the patient; 3, when there are adhesions they will remain as long as a pathologic gall bladder is present to keep up the irritation; 4, it is a well-known fact that intra-abdominal adhesions gradually weaken, stretch and disappear when there is no disturbing element; 5, the value of the gall bladder as a reservoir for the bile is *nil,* and functionally it serves no more useful purpose than does the vermiform appendix; 6, after a gall bladder has been as profoundly diseased as it usually is when made the object of surgical attack it never regains its normal state and is henceforth not only valueless but, on account of its defective drainage, is constantly subjected to the risks of fresh infection; 7, the cholesterin, which is the principal element of almost all stones, is only elaborated in such a quantity as to do harm by the epithelium of the gall bladder when infected, being due to degeneration, therefore, when removed, all danger of future stone formation is at an end; 8, it is estimated that at least 5 per cent. (Mayo) of the cases of serious disease of the gall bladder are followed eventually by carcinoma; removal will take away this menace.

A number of gentlemen who have written on this subject seem to regard cholecystectomy as especially dangerous where adhesions are numerous. Some of the most satisfactory results I have obtained have been in this class of cases and, as all know, adhesions are inimical to complete relief when cholecystostomy is performed. A gangrenous gall bladder is safer outside the abdomen, and, even though the operation requires a little longer time than simple drainage, I believe the risks of a slightly longer operation are more than offset by the more favorable condition following complete removal. When the operation is for empyema, more or less destruction of the mucous membrane of the gall bladder and cystic duct is to be expected and retention of such a viscus will probably result in only partial relief.

It must be admitted that there are some conditions where the simplest and quickest surgical procedure possible to give temporary relief is as much as the patient can bear. Here simple drainage may be done, to be followed later by cholecystectomy if complete relief is not obtained. In cases where there is temporary or permanent closure of the common duct this operation is, of course, not to be thought of.

To some the existence of infection has been deemed a contraindication to cholecystectomy, since it is in violation of the cardinal principle in these cases, drainage. It is as easy to secure drainage when the gall bladder is removed as when it is retained. In four of my cholecystectomies, instead of ligating the cystic duct, W. J. Mayo's method of removing the mucous membrane has been used. The greater part of the gall bladder is removed. Beginning a short distance above the cystic duct the mucous membrane is stripped off and removed down into the duct. Then a purse-string suture is introduced around the cuff of muscle and peritoneum and tied over the end of the drainage tube. It drains as perfectly as when the entire organ is retained, and closes quickly when the drainage tube is removed.

When the common duct is patulous and is not constantly being infected afresh from a septic gall bladder it seldom needs external drainage. The voluminous flow of bile through the hepatic and common ducts tends to sweep infective material into the bowel. The need of drainage in these cases is usually not to be found in the ducts but in the infected and crippled gall bladder. Surgeons who have once tried cholecystectomy are constantly resorting to it for an increasing number of indications. The operative mortality, immediate and remote, seems no greater than that from cholecystostomy when both complicated and uncomplicated cases are taken into consideration. The rapidity of convalescence is certainly a powerful argument in favor of the more radical procedure. The strongest inducement in favor of cholecystectomy is the complete relief it gives, in striking contrast to the painful and dragging symptoms which so frequently remain after cholecystostomy.

THE CALL FOR EXPLORATORY OPERATION IN THE GALL-BLADDER REGION.*

F. A. DUNSMOOR, M.D.
MINNEAPOLIS.

The surgical age is on, and it is to the credit of the profession that this is true. It were trite to cite cures where drugs have been used to worse than waste precious time, followed by an operation which has brought relief, comfort and usefulness to patients who were a burden to themselves and friends. It is not our intention to criticise former practice of the internalists or surgeons. It is not ages ago that each was barbarous in both senses of the word. It is an old tale to this body to be told of the safety of abdominal incisions when absolute cleanliness and skill attend the operation. Hence this word as advocating such procedure as a simple means of diagnosis and a long step toward the best method of cure.

The diagnostician has continually in his mind's e
a map of the surface of the body, and knows what no
mally should be hidden beneath each square inch thereo
irrespective of the attitude, posture or part presentin
He reviews the physiologic functions and possible
probable pathologic lesions, and still may have anoth
guess coming. Nevertheless, a writer for one of ou
medical journals has said that no man should make a
abdominal section until competent to certainly forete
the exact pathologic condition for which the operatio
was to be made. Mindful of this demand by critics, th
writer hesitated to advance the suggestions of this essa

Dividing the abdominal cavity equally into two zone
the upper will always be the field of most difficult su
gical maneuvers, whose tumors are more frequently m
lignant and their cure impossible; while the lower pro
vides the opportunities for brilliant recoveries to th

Ochsner, J. E. Moore and De Forest Willard.

chondrium, because of the important glands, ducts and vessels therein contained.

Neoplasms or inflammatory products in the pelvis have fixed walls for their protection, with only slight disturbance from excretory functions, while pathologic changes in the proximity of the chest wall are subject to continued irritation due to respiratory movements, as well as pressure from the almost continual variation of body posture.

Often the resulting exudates and adhesions of salpingitis are painless, while adhesions from an old or new pleuritis give rise to stabbing pain from movements, like sneezing, coughing or muscular effort.

Any maneuver separating the adhesions would be of great benefit. Similar results obtain when the lesion is immediately below the diaphragm. There, however, pain is frequently associated with gastrointestinal disturbance and concomitant involvement of the liver, pancreas, large glands, or a movable kidney. These facts indicate a greater demand for surgical attention to manifestations of disease here than in the famous pelvic region.

An incision through the upper right semilunaris is practically bloodless and has, *per se*, no mortality, and yet what a field for investigation! Beneath the space not larger than the palm of one's hand, and with the center midway between the tenth rib and the umbilicus, we find the gall bladder, hepatic and pancreatic ducts, part of the liver and kidney, the pyloric end of the stomach, part of the duodenum, colon, omentum, mesentery and important vessels. When diseased, many other important structures have occupied this space. Clinically, we are supposed to be able to diagnose gallstones. Thirty years' personal observation, W. Mayo's St. Mary's Hospital reports, and postmortem findings the world over, show that they are oftener overlooked than found. Pancreatic disease is much more obscure. Abscess of the liver, or hydatids, cancer of pylorus, usually definitely proclaim their presence. There remain, however, many inflammatory and non-malignant conditions which leave vague contradictory or puzzling symptoms, following one or more acute attacks of various affections incident to this location. Selecting only those not benefited by drugs or massage, but aggravated by driving, riding, jolting or by ordinary manual labor, we have abundant reason for exploratory and radical surgery in this region. The arrangement and anatomic support of the upper abdominal viscera are such that the danger of a hernia following section of the abdominal wall here is much less than below the umbilicus. The same causes make greater probability of permanent cure following division of adhesions.

It has been quite common to discourage any operation in the region of the gall bladder until the surgeon was confident of finding stones. The same may be said of operations looking to examination of the kidney. Pancreatic disorders and disease of the blood vessels are free from liability of harm from such investigation through an incision at this point, or through the linea alba. There are many cases in which a reasonably certain diagnosis of disease of the gall bladder is made, when it is not expected that calculi are present; but we may wish to drain through the kidney pouch for empyema, or chronic catarrh, or examine for results from trauma.

When we contemplate the important organs which may be readily and with great safety thoroughly examined through a window in the right hypochondrium, we shall find at least a reasonable excuse for the exploratory incision, which has so often been the open door for relief of undiagnosed pathology of the lower abdomen.

Case 1.—J. S., Kidder, N. D., farmer, aged 28, family history negative. In spring of 1896 had an attack of vomiting with pain over stomach which lasted two months. Has had severe recurrence each year, one beginning a year ago, and has been constant since. Operated on May, 1902. No gallstones, but vermiform appendix inflamed and adherent to gall bladder and liver. Appendix removed, adhesions separated and colon replaced in normal position. Good recovery and present health good.

Case 2.—G. F. P., Wilmot, S. D., senator, aged 40. For two years has had "spells" of pain in right side in hepatic region. When the attack was severe the pain would extend from shoulder to groin and be attended with jaundice. Present attack began one month ago with icterus and putty-colored stools. Operated on Sept. 7, 1902. No calculi in bladder or ducts. Evidence of local inflammation and adhesions. Latter broken up. Uneventful recovery.

Case 3.—Mrs. N. S., housewife, aged 23, emaciated, anemic, jaundiced and neurasthenic. Had hepatic colic three years ago, passed stone; several attacks since; last three weeks ago. Patient constipated, has clay-colored stools, pain over gall bladder, usual gallstone symptoms. Operated on at Asbury Hospital March 11, 1901. Incision right of rectus, gall bladder found twisted and bent or doubled on itself. Covered with adhesions of omentum to gall bladder and liver. No stones present, all adhesions divided; gall bladder liberated, wound closed; uneventful recovery, icterus gone. Good health reported November, 1902.

Case 4.—C. S. P., Estelline, S. D., male, farm owner, aged 45, member house of legislature. Entered Asbury Hospital Oct. 14,1901. Father died at 71 of "heart failure"; mother living and well; two brothers died in infancy; one sister had consumption at 22. Patient has always been well until some time in June, 1900, when he had very severe pain in right hypochondriac region, requiring opiates. Severe pain ceased one month ago, leaving a sore spot to right of ensiform cartilage. Sept. 1, 1901, he had another attack, and again October 1. Operated on Oct. 15, 1901. No gallstones in bladder or ducts. Extensive adhesions; frail-like mesh work extending widely under lower surface of liver, extending to stomach covering in gall bladder and intestines. Have seen this patient twice during past two years, has gained 30 pounds and has had no further trouble.

Case 5.—Miss B., Drayton, N. D., student, aged 19. Family history good. Present illness began four years ago with pain in right side. No tenderness until last year, when point of pain located between crest of ilium and lower rib. Patient neurotic and has lost much flesh the last six months. Operated on at Asbury Hospital April 5, 1902. Incision in upper right semilunaris, found omentum massed in right side with evidence of inflammation extending from colon to liver. Coils of intestine and omentum adherent to right mural peritoneum. No stones in gall bladder. Appendix removed. Patient had peritonitis for two weeks and convalesced slowly. A week later had an attack of dyspnea, feeble pulse, lividity and was evidently near dying. Had dilated heart. Recovered in two weeks, so as to be able to return home. Returned to hospital Nov. 1, 1902, with pain in right ovarian region. Has gained 40 pounds in flesh and has bright, rosy cheeks. Was put under local treatment of douche and external massage for two weeks with no benefit. Operated on November 16, removing left ovarian cyst three inches in diameter, also removed right tube for extensive salpingitis. Is about the hospital, complains of neuralgic pains in various parts of the body.

This group of cases simply shows benefits from so-called liver cases which drugs and diet did not help. Case 3 is evidence that gallstones may be expelled by way of the bile ducts and leave more pathology behind than their presence manifested.

In Case 4, although the appendix was involved, the condition and symptoms warranted the conclusions that the pathologic conditions began at the gall bladder and a general peritonitis followed, finally involving the pelvic organs. Had this case been explored four years earlier, I have no doubt the ovaries could have escaped disease and removal.

DISCUSSION

ON PAPERS OF DRS. DAVIS AND DUNSMOOR.

Dr. William J. Mayo, Rochester, Minn.—Dr. Dunsmoor has called our attention to the necessity of frequent operation in the region of the gall bladder. Let us not forget that there are two kinds of diagnoses; one that is exact, in which we know what we are going to do, and the other a diagnosis, which must be very commonly made, in which we can not say exactly what the condition is, but in which we do know that a condition exists which can probably be relieved only by surgical interference and, therefore, a diagnosis that would necessitate surgical interference need not necessarily carry with it an accurate diagnosis of the condition that we expect to find.
